This data is especially valuable, as the winning car had only a 2-cylinder motor and the greatest piston displacement. It is therefore probable that this motor was only run at a moderate number of revolutions per minute.

With these results before us, it should be easy to now fix upon the maximum displacement which may be considered a reasonable one for a touring car.

The argument against this will, of course, be the usual one that it does not limit the speed at which the motor can be run. For instance, one maker may, under normal conditions, run his motor at a 1,000 revolutions, while in the contest he may run it up to 1,200 or more. However, to guard against this there is a limitation of fuel consumption, as it is evident that whatever may have been the revolutions of the motors fitted to the cars above referred to, there is a very little margin over the fuel allowance. Had the engines of cars with a smaller piston displacement beaten those of larger displacement, it would have probably been evidence that the smaller engines were run at excessive speeds. However, this is not the case, and with the limitation as regards fuel consumption, it would therefore appear that no excessive motor speed is beneficial.

Another possible argument against the no-weight limit may be that it will encourage the development of freak machines. This difficulty may be met very easily by a regulation that all cars entered must be in every detail the standard commercial models, and that exactly similar machines must be shown to have been on the road for at least three months before the date of contest.

I also suggest that every car must, before being accepted, be driven for say 50 miles under observation to prove its capability of running on the fuel allowance.

I would also suggest that a separate class be constituted for 2-cylinder cars, or a special prize for the best performance of such cars, as I take it that one of the objects of the competition is to prove the capability of cheap and reliable cars, and, therefore, some encouragement ought to be given to a type of motor which this late contest has shown to be both economical and speedy, as we find that a 2-cylinder car takes the first place as regards speed, and another 2-cylinder car the first place as regards fuel consumption.

Yours truly,

September 25.

J. S. CRITCHLEY, M.I. Mech. E.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I am writing to ask if any of your correspondents can give me some information upon a subject which seems to me to be of considerable interest. Lately there has been a good deal of attention aroused by the Tourist Trophy Race in the Isle of Man.

About the same time the notice of the automobilist public was drawn to the fact that several new associations or unions of motorists had sprung up, if not actively hostile to, at all events by no means the friends of, the A.C.G.B.I. I may mention here that I am not a motorist myself, *i.e.*, I do not possess a motor car, nor can I drive one, but several members of my family are keen upon motoring, so I naturally take considerable interest in the automobile movement. Now by Rule 5 of the Tourist Trophy Rules, which I imagine were drawn up by the A.C.G.B.I., "The fuel to be used shall be provided by the club, and shall be petroleum spirit having a specific gravity of 0.695–0.705 at 60° F."

Now this rule absolutely restricted the Tourist Trophy Race to those cars which used petrol as a propellant agent. Is this because petrol cars are now the only make of cars to be considered? I would like to know why the Tourist Trophy Race was so restricted? Are there not makes of cars on the market which use paraffin and other things as propellant agents? The Motor Yacht Club admitted paraffin-driven, coal-driven, and producer-gas-driven boats to its trials. The coal-driven boats, I noticed, obtained the Gold Medal, each in its class. Why should not the Tourist Trophy have shown a like catholicity? Some time ago I noticed a gentleman writing somewhat strong, not to say indignant, letters to the motor car papers, denouncing the A.C.G.B.I., and saying that instead of being called the "Automobile Club" it ought to be called the "Petromobile Club." I fancy the gentleman had some interest in some make of car which did *not* use petrol as a fuel, hence the heat

of his indignation was all the greater! But may not his observation contain a grain of truth? Is the Automobile Club an association of manufacturers of one type of car, or is it really representative of the whole body of motorists? Is it not considerably to blame for the associations which have sprung up against it, owing to its being too

narrow-minded and prejudiced in the favour of one type of car? As a non-motorist and a looker-on, I appeal to you or to your correspondents to give me an explanation.

Yours faithfully,

Bracknell, Sept 24th.

"INQUIRING IGNORANCE."

TURIN TO DIEPPE UNDER TWENTY HOURS.

THE Fiat cars have established such a splendid reputation both for speed and reliability that no record which they may now make will come as a surprise to our readers. A telling example, however, of what the machines, as turned out by the company, can be relied upon to do with certainty, as soon as they are put together, perhaps counts for more than the winning of any pre-arranged race or reliability test for which special cars have been previously prepared and tuned up during weeks or months. These observations are suggested by a very fine performance of a 24-h.p. Fiat car, of which Mr. Miller and Mr. D'Arcy Baker took delivery direct from the works at Turin on the 19th of last month, and of which we have received from the *voyageurs* the following interesting particulars. Owing to exigencies of time the chassis had not been then even given the preliminary test run which the makers invariably subject their vehicles to before putting them into the hands of a purchaser. The car was simply put together, and Mr. Miller, with Mr. D'Arcy Baker and Commander and Mrs. de Satje started off forthwith for a trans-European tour upon it. They made a splendid run. The travellers selected the Mont Cenis route into France and scaled the tremendous road that goes over the mountain, not once being compelled to have recourse to the first speed, and taking the greater part of the road, the gradients of which are notorious, on the third. The car had left Turin at 2.40 in the afternoon, Susa was reached at 3.30 p.m., and the ascent of Mont Cenis commenced at 2 minutes to 4, the summit, 6,500 ft., being reached at a quarter to 5. From that point they had, of course, a long and winding run down, and Lanslebourg, the first French town over the frontier, was reached by 12 minutes past 5. After this the journey lay along the splendidly picturesque road through Modane to St. Jean de Maurienne, where the beauty of nature was to

some extent unpleasantly cancelled by the want of beauty of the road surface, which, however, gave the travellers more opportunity for enjoying the mountain views. After the latter place, however, the roads gradually improved, with the fine long stretches of 12 and 15 kilometres without a turn, characteristic of the grand "Chaussées" of France, where some very fast travelling indeed was made. In fact, on two occasions the car performed runs of 265 kilometres in a fraction over 5 hours, attaining on some stretches, where it was timed over short distances, a speed of 60 miles an hour. The first night was passed at Aix-les-Bains, and the second day's run terminated at Chalons—a departure from the original intention, which would have brought the car to Macon. The account given by travellers of the hotels at Chalons, at which place, apparently, they stopped on this occasion for the second time in their experience, are certainly calculated to make all motorists avoid that city in future. The journey was continued to Paris, and from Paris to Dieppe, with the same total—we might almost say phenomenal—absence of accident, considering the distances covered and the speeds attained. The times of the different stages of which the journey consisted were as follows:—

	kiloms.	h. m.
Turin to Aix-les-Bains	193	in 4 20
Aix-les-Bains to Chalons (sur Soane) ..	265	" 5 1
Chalons to Paris	354	" 6 39
Paris to Dieppe	168	" 3 10
.....	980	" 19 10

Mr. Miller speaks most enthusiastically of the Michelin tyres with which the car was fitted. They gave absolutely no trouble the whole of the journey, though several very bad stretches of road were encountered, and on reaching Dieppe they scarcely showed any appreciable wear.

To Sound or Not to Sound the Horn.—If county court judges are generally going to follow the example of His Honour Hans Hamilton of Clitheroe, motorists will find themselves between the devil and the deep sea, though which is the devil and which the deep sea we leave to our readers to decide. On a recent occasion a motorist duly blew his horn on approaching a horse-drawn conveyance, whereupon the horses ran away. There was a smash, and both of them were injured, one of them subsequently dying. For thus sounding his horn Mr. Arthur Thompson, the owner of a motor car, was ordered to pay damages amounting to £55 11s. 2d. Now the law prescribes that when a motorist is approaching a horse-drawn vehicle, and upon other occasions, "he shall give audible warning of his approach by sounding his horn," and if he fails to do this he can be fined up to £20. What, therefore, is the unhappy motorist to do? To speak seriously, the decision is such a preposterous one, and will have such far-reaching consequences if allowed to count as a precedent, that we sincerely trust that an appeal will be lodged against it.

The Enquiring Mind.—We referred some time ago to the sad case of the inquisitive individual who went out to

look for a leak of petrol with a lighted match. There appear to be some equally inquisitive and, if possible, less intelligent individuals inhabiting the port of Newhaven. The railway companies, not unreasonably, insist that whenever a motor car is taken on board the petrol should be emptied out of its tank. A car which was to be shipped from Newhaven to Dieppe complied with the requirements and ejected its petrol on to the surface of the River Ouse in the port in question. Some inexperienced youths who were rowing by in a boat thought they would like to see whether the petrol would burn on the surface of the water, and accordingly applied a match to make the experiment. It was supremely successful. Instantly their boat was enveloped in flames which rose to a considerable height in the air, setting fire to the boat, and the experimenter's clothing, who leaped into the water to cool himself. When rescued he was found to be severely burned, though by poetical justice, which is not always in evidence, the other occupants of the boat escaped unhurt. We trust this taste of the effects of the old "Greek fire," whose leading characteristic was that it burned on the surface of water, will make the Newhaven experimenter more cautious in future.

THE TOURIST TROPHY RACE QUESTION.

So much greater, and so much more general, is the interest that is now taken in the Tourist Trophy type of race—the first contest of the kind having proved so pre-eminently successful—that many of our readers may find it useful to have their attention drawn to the numerous special articles, dealing with this important subject, that have appeared in our pages. The following summary will be found to constitute a handy index to the nature of these previous articles, the continuation of which we have again been compelled to hold over to another week:—

RACES, RECORDS, AND TRIALS.

Henry Edmund's Hill-Climbing Challenge Trophy Race.—The entries and order of starting for this race, arranged to take place at Blackdown Park, Fernhurst, Sussex, in the private grounds of Mr. F. S. Philipson Stow, on Wednesday of this week, were as below. Car No. 1, Mr. E. Campbell Muir, holder of Trophy, decided not to defend:—

No.	Entrant and Car.	Driver.
2	F. A. Potts, 30-h.p. Daimler	C. Grinham.
3	E. Gascoine, 12-h.p. Wilson-Pilcher	E. Gascoine.
4	Chas. Sangster, 40-h.p. Ariel-Simplex	C. Sangster.
5	Harvey du Cros, jun., 30-h.p. Ariel-Simplex	H. du Cros, jun.
6	A. Huntly Walker, 70-h.p. Darracq	A. Huntly Walker.
7	S. N. Bankart, 24-h.p. Rochet-Schneider	Morgan Donne.
8	F. R. S. Bircham, 24-36-h.p. Itala	F. R. S. Bircham.

The length of the hill is 1,650 yards, and includes a grade of 1 in 4½ for nearly 400 feet at a severe bend in the road, and therefore provides a very hard test for a car even of high power.

Manchester Hill Climb.—The Manchester Motor Club on Saturday last held a hill-climbing contest on the Snake Hill, near Glossop, about 14 miles from Manchester, near to the Derbyshire borders. The measured stretch on the hill was 3 miles, in which the average gradient was about 1 in 14, with at points 1 in 8 to 1 in 6. Entries for 35 cars were received, of which 31 competed, in the 5 classes. The starting-point was at the Royal Oak Inn, and the chief results were as follows:—

Class 1.—(1) Mr. W. McNeil (7-8-h.p. Cottureau). (2) F. Sturgess (6-h.p. De Dion). Won by 1m. 37½s.

Class 2.—(1) J. Richardson (8-10-h.p. Coventry Humber). (2) A. Huntley Walker (10-h.p. Darracq). Won by 13½s.

Class 3.—(1) A. Huntley Walker (15-h.p. Darracq). (2) C. H. Cooper (16-20-h.p. Humber). (3) W. Dyson (15-h.p. Darracq). Won by 1m. 54s.

Class 4.—(1) A. Huntley Walker (15-h.p. Darracq). (2) 16-20-h.p. Argyll. Won by several minutes, the Argyll carburettor having got choked up.

Class 5.—A. H. Walker "walkover," 60-h.p. Mercedes.

Impromptu Hill Climb.—Subsequent to the motor cycle hill climb of the Sheffield A.C. at Grindleford last Saturday, an impromptu handicap test for cars was held on the hill, when the following were the times accomplished:—

C. D. Leng, 16-24-h.p. Fiat (4 cyl.)	...	7	4
J. H. Pickford, 24-h.p. Germain (4 cyl.)	...	7	27
J. H. Hall, 12-h.p. Gladiator (4 cyl.)	...	8	29
T. J. Fryer, 10-h.p. Hallamshire (2 cyl.)	...	8	50
Dr. Fletcher, 6-h.p. Wolseley (1 cyl.)	...	11	25

The handicap results have yet to be worked out.

Dewar Non-Stop Challenge Cup.—On Monday last Mr. Rowland Morewood, secretary of Mors, Limited, started on a 14-h.p. Mors car to compete for this challenge cup over a distance of 2,000 miles. The trophy was presented by Sir Thomas Dewar, with the provision that it should be run for by touring cars covering a distance of 2,000 miles in the quickest time, keeping within

the legal speed limit, and without stopping the engine. The car for which the trophy is at present held is a Clement-Talbot, the time occupied over the distance being $124\frac{1}{2}$ hours. The route to be taken by Mr. Morewood was the same as last year, from London to Perth and back twice, by the Great North Road *via* Grantham, Doncaster, York, Durham, Gateshead, Newcastle, Alnwick, Berwick, Edinburgh, Dunbar, Falkirk, and Stirling. The final run was to be from London to Portsmouth and back, making a total distance of 2,019 miles. At Perth Mr. Morewood was invited to lunch with the Lord Provost and Council and Sir Thomas Dewar. Unfortunately a collision with a cart 19 miles from Edinburgh terminated Mr. Morewood's present attempt.

Errata.—We regret that our special table, giving in a concise form the full results of the Tourist Trophy Race, contained incorrect times for the second lap of the winning Arrol-Johnston car (No. 53), and for the fourth lap of the Vinot car (No. 52). The correct times were: For the second lap of the Arrol-Johnston car (No. 53), 1h. 32m. $21\frac{1}{2}$ s. = 33.8 m.p.h.; and for the fourth lap of the Vinot car (No. 52), 1h. 32m. $38\frac{1}{2}$ s. The maximum speed for any lap was, therefore, 34.5 m.p.h.

THE Ryknield Engine Company, whose All-British car made, we believe, a non-stop run throughout the Tourist Trophy Race, write pointing out that the price given in our table on page 1166 of our last issue is for the complete car and not for the chassis, which is sold separately, at £385.

The *Manx Sun*, which gave its unstinted support to the Tourist Trophy Race throughout, actually had a special

edition printed and in circulation on the evening of the race, containing an account of the proceedings, and a full table of results giving the times for each competitor.

Vanderbilt Cup American Eliminating Trials.—Last Saturday, the 23rd instant, the American entrants for the Vanderbilt Race, which takes place in Long Island on October 14th, ran over the Cup course for the purpose of selecting the representative team of five for America. The course, a map of which we have already published, was the same as the Cup course, except that the race in this case was only four times round, making a total of $113\frac{1}{2}$ miles, instead of the ten times as originally planned, giving a total of 283 miles. This reduction was mainly in order not to inconvenience the resident population in the district by having two long races so close together. The start was from Mineola. In the ballot for order of starting the 50 h.p. Haynes car drew first place, there being twelve in all entered. Of these ten actually started in the following order, the respective official numbers being given:—

	Driver?
1. E. Haynes's 50-h.p. Haynes ...	Frank Nutt.
2. A. E. Pope's 60-h.p. Pope Toledo	Bert Dingley.
3. L. M. Palmer's 40-h.p. Matheson	R. Mongini.
4. R. H. White's 40-h.p. White ...	W. C. White.
5. Dr. Thomas's 90-h.p. Locomobile	Joseph Tracy.
6. J. L. Breese's 60-h.p. Christie ...	Christie.
7. E. D. Shurmer's 40-h.p. Royal Tourist	R. Jardine.
8. H. S. Houpt's 60-h.p. Thomas...	M. Roberts.
9. E. H. Green's 60-h.p. Franklin...	W. F. Winchester.
12. A. A. Pope's 90-h.p. Pope Toledo	Herbert Lytle.

The non-starters were:—No. 10, Matheson's 40-h.p. ~~Matheson~~ to be driven by Tom Cooper, retired, owing

MONT VENTOUX HILL-CLIMB.—As we announced last week, Cagno, on a Fiat, was the winner of this lengthy hill-climb in $19\frac{1}{2}$ minutes. Our photograph shows Cagno finishing towards the top. This picture has an increased interest from the fact that it was one of the last photographic plates exposed by M. Rol, the well-known member of the staff of "Les Sports," who was subsequently, as we announced last week, killed during his descent on Collomb's car.

to the radiator being broken during the night, and G. A. Weidly's 60-h.p. Premier, which was to be steered by Fisher, but was not in place in time to start.

The cars were got off expeditiously and the first starters were soon round the circuit entering upon their second lap. During the first round Christie, who had displaced his mechanic Owen, and personally drove Breese's Christie car, was travelling especially fast at the commencement, but when taking an acute turning at an ill-judged speed the back of his car swung round and crashed against a telegraph post, damaging his right back wheel severely. He, however, remedied the mischief and pluckily re-started, but the race was hopeless under the circumstances and he retired in his second round. Shurmer's car had a remarkable experience and escape. At one of the many dangerous corners where cinders and sand had been spread to prevent skidding, the car had a bad slide and turned turtle. Fortunately both driver and mechanic escaped without injury and the machine with the assistance of the bystanders was righted and the steering gear which had been damaged repaired, the car within a few minutes of the occurrence being again on its way round the course, this car actually making the second best time of the day. Lytle on his 6-cylinder Toledo was getting over the ground splendidly, but unfortunately had to abandon the contest owing to a fracture in his frame. Walter White's 40-h.p. steamer was eliminated through trouble with his differential. At the finish of the fourth round the 5 cars which qualified for taking part in the race on October 14th were:—

1. Dr. Thomas's Locomobile (No. 5), 2h. 1m. 49s.
2. E. D. Shurmer's Royal Tourist (No. 7), 2h. 19m. 8s.
3. E. Haynes' 50-h.p. Haynes (No. 1), 2h. 23m. 32s.
4. H. S. Houpt's 60-h.p. Thomas (No. 8), 2h. 29m. 40s.
5. A. L. Pope's 60-h.p. Pope Toledo (No. 2), 2h. 50s.

In spite of these results, however, according to Reuter's telegram, the Cup Commission has rejected three of the qualified cars, the following being selected to compete in the Cup race: A. L. Pope's Pope Toledo, Dr. Thomas' Locomobile, A. L. Pope's Pope Toledo, J. L. Breese's Christie, and R. H. White's White Steamer.

From a later telegram we learn the committee have re-considered their first decision, and have named the original cars which qualified (as given above) to run in the race, but they have authorised Lytle to replace Dingley on the Pope Toledo, as they state the trial was one of cars, and not necessarily of drivers.

The race has given rise in several quarters in America to the question as to the use and advisability of motor racing of this character. Evidently the same feeling is

growing in the United States as in England, that pure speed contests with speed machines are rather to be deprecated than encouraged.

The Future of the Gordon-Bennett Cup.—In regard to the allotment of the Gordon-Bennett Cup to a big tourist car competition, considerable misapprehension appears to exist in respect to its being allocated for that purpose by Mr. Gordon-Bennett. As we announced last week, the whole question will be submitted to the representatives of the various clubs interested before anything will be decided, and Mr. Gordon-Bennett, in an interview, has confirmed this statement. The Marquis De Dion, who is particularly in favour of an extensive endurance competition, suggests that in the event of the Cup being allotted to a contest of this character, entries should be reserved entirely to constructors, that the distance should be 5,000 kiloms. at least, that each competing car shall be minutely stamped in all its parts, and that every repair or replacement shall be strictly noted—in fact, that it should be run practically on the stricter lines adopted in Great Britain. We would suggest, in addition to the Marquis's proposals, that, in order to retain the international character of the competition and to continue the main object for which the trophy was created, each car should be entered as before through the representative club of its country, and that the whole of the parts should, in similar manner to the rules regulating the Gordon-Bennett trophy for racing vehicles, be entirely made in the country of origin.

A Goggle Competition.—A competition of protectors for the eyes when motoring, as announced some time ago, is shortly to be adjudicated upon in France. Originally started by M. Cormier, about 2,000 francs have been offered as prize money. Eleven entries have been made for goggles, and M. Huillier has entered a device for fixing in front of a car. The entries of goggles have been made by MM. André Fériel, Eugène Jeantel, Paul Morel, E. Peyrot, fils., A. Miret et Lecluc, A. Drouet, Dr. Letourbe, M. Meyan, Mirovitch, Emile Dumoulin, and Lanjeais.

For the Annual Hill Climbs on Chateau Thierry and Gaillon (which are to be held this year on October 1st and 15th respectively) a category for tricars has been instituted, amongst this class of vehicle being two Contal tricars in the $\frac{1}{2}$ litre class. A class for commercial vehicles is also a new feature.

Who Really Use Our Roads?—A recent census has been taken by our contemporary the *Car* of the number of vehicles proceeding along the main roads out of London. The census was taken on different days, generally from 10 in the morning till about 6 in the evening, on the following roads, when there was no reason for any abnormal traffic, the results being given annexed thereto:—

	Cycles and automobiles.	Horse- drawn vehicles.
Great North Road (a mile from Barnet) ...	151	131
Bath Road (4 miles from Hounslow) ...	191	95
Brighton Road (2 miles from Merstham) ...	257	123
Exeter Road (2 miles from Staines) ...	226	108
Portsmouth Road ($1\frac{1}{2}$ miles from Esher) ...	285	120

It will be seen, therefore, that while the total of self-propelled traffic on all these roads amounted to 1,110, there were only 577 horse-drawn conveyances.

It is reported in the *Musical News* that the celebrated Sousa has written a new motor march in which are to be introduced "motor-horn effects." Whether they will be euphonic or not may be a question, but one of the most generally recognised "motor-horn effects" is a sudden concentration of police attention on the spot where they are heard, so if the new march is brought to this country, we may find that the concert room in which it is "given" will at once form a centre of police interest. No doubt Mr. Cathcart Wason will ask a question about the matter as soon as Parliament reassembles.

COMPARATIVE FUEL-CONSUMPTION ON THE OXFORD ROAD.

Mr. Percy Northey, with his mechanic, Durlacher, on the 20-h.p. Rolls-Royce car, that secured second place in the Tourist Trophy Race, and was one of the cars tested on the Oxford Road.

A Daybreak Test on Tourist Trophy Lines.—Very interesting and instructive in their way were some fuel-consumption tests which we assisted in conducting during the early hours of Friday morning (Sept. 22nd), on the "average road" quoted by the A.C.G.B.I. in their Tourist Trophy Regulations for this year's race—the orthodox road from London to Oxford. The actual cars used for this purpose were the two Rolls-Royce vehicles that took part in the great race in the Isle of Man on the 14th inst., when car No. 1, driven by the Hon. C. S. Rolls, was unlucky enough to be compelled to retire with a broken gear-wheel, but car No. 22, driven by Mr. Percy Northey secured second place with the remarkably high average speed of 33.6 miles per hour, and a mean fuel-consumption of only 24.8 miles per gallon.

On the present occasion, car No. 1 was again driven by Mr. Rolls, but car No. 22, which, it will be remembered, has slightly smaller cylinders (10 per cent. less piston area) and is geared about 12 per cent. lower, was driven by Mr. Claude Johnson. The objects of the tests were numerous, but they may be said to have been principally directed towards obtaining some idea of the relative T.T. capabilities of the two R.R. cars, and of instituting a rough comparison between the "average road," that has for some months served as a British standard unit to manufacturers, and the Manx racecourse.

Both cars—the 1906 type of Rolls-Royce light 20-h.p. vehicle—were running with their customary smoothness, quietness and freedom from all unnecessary friction throughout the transmission mechanism, but for obvious reasons it was necessary that the speed should be lower than in the Isle of Man. This in itself might be expected to favour fuel economy, and would indeed have done so were not its effect much more than counterbalanced by the exigencies of the traffic encountered on the route. Two unavoidable influences, in fact,

had the effect of tending to render the tests somewhat misleading, and it is therefore necessary to point out most clearly that the fuel consumption was largely in excess of what it would have been if a clear road could have been maintained, and if the entire route from London to Oxford had been available for the purpose. As it happened, frequent applications of the brakes and a number of stoppings and restartings were found imperative, while only a portion of the route could be utilised, and that portion included all the hilly country.

The start was made from the 10th milestone out of London, the road was for the most part dry and very dusty, and the run was made to a point half a mile beyond the 52nd milestone—a distance of 42½ miles. Each car carried two passengers, in addition to the driver, and an equivalent weight was carried to represent a fourth person. Prior to the start, the level of the petrol in both tanks was carefully noted, and subsequently—both after the outward journey, and again when the return trip was completed—they were refilled to precisely the same level in accurately measured doses. The amount of fuel used, and its equivalent value expressed in miles per gallon, is shown in the following table:—

	Car No. 1.		Car No. 22.	
	gals.	miles per gal.	gals.	miles per gal.
Outward journey (42½m.) ...	1.72	24.7	1.69	25.1
Return journey (42½m.) ...	1.935	22.0	1.72	24.7
Total trip (85m.) ...	3.655	23.3	3.41	24.9

It is significant to notice that both vehicles consumed more fuel during the return than during the outward journey, this being chiefly due to the increased traffic on the roads during the later hour of the morning.

MOTOR CYCLING.

The Auto Cycle Club and Permits.—Dealing with the competition held by the Motor Cycling Club on 25th August, for which no permit had been obtained from the Auto Cycle Club, the Committee of the A.C.C. have passed the following resolution:—

"That the Motor Cycling Club, having committed a breach of the rules of the Auto Cycle Club by holding on the 26th August, 1905, an open meeting without a permit from the Auto Cycle Club, the Motor Cycling Club be and is hereby suspended for a period of twelve months from the 18th September, 1905."

It has also been resolved as follows:—

"That Mr. J. Van Hooydonk, having committed a breach of the rules of the Auto Cycle Club by taking part on the 26th August, 1905, in an open competition which was not held under the rules of the Auto Cycle Club, be and is hereby struck off the register of the Auto Cycle Club, and his licence is hereby suspended for the period of one year from the 18th September, 1905."

The Committee of the A.C.C. further announce that Messrs. A. Candler, C. W. Brown, R. G. Booth, E. March, and Chester Fox have each of them been guilty of a breach of the rules of the Auto Cycle Club by taking part on the 26th August, 1905, in this competition, and notice of the resolution to this effect has been sent to the Licensing Registrar.

These resolutions refer to the matter which has been freely discussed recently in the columns of the Press in connection with the claim by the Auto Cycle Club to license all motor cycle meetings and motor cycle riders—an authority which the Motor Cycling Club and its members dispute.

THE Annual Dinner of the Auto Cycle Club will be held in the first week in January, when it is hoped the Hon. Arthur Stanley, the President of the club, will occupy the chair.

Auto-Cycle Club Penalty Run.—Remarkable success attended this run on Saturday last, which was confined to private members of the Club and its affiliated Clubs, the start taking place from the Castle Hotel, Woodford. We gave last week particulars of the penalties incurred, and also of the route from Woodford, to Littlebury and back, a distance of 68 miles. Out of 65 entries 57 actually competed, and no less than 32 made non-stop runs. In addition four clubs sent teams to compete for the special prize offered for Club Teams. The road from end to end was very carefully marshalled, so that although each competitor was required to report every stop which might occur, the likelihood of any stop being forgotten was in a measure provided against by the number of controllers who were scattered along the road. The whole of the competitors had been dispatched before 3 o'clock, and the first arrivals back were timed for soon after six, the latest time for classing being 8 o'clock. Very great assistance was given by the Essex Beaumont Motor Club, and the judges were Messrs. Robert Todd and G. F. Sharpe. At the concert which was held subsequently at the Woodford Castle Hotel, the official results were as far as possible announced. The awards made are as follows:—

Team Prize: (1) Essex Beaumont Motor Club. (2) Woolwich, Plumstead and District Motor Club. (3) Ilford and District Motor Club. (4) Coventry Motor Cycle Club.

Those who made non-stop runs were, under the heading of their respective clubs, as follows:—

Auto Cycle Club.—E. Musgrave, 10-h.p. Lagonda tricar; W. H. Hayes, 34-h.p. Rex; H. Alldridge, 3-h.p. Taffair; M. J. Tuchmann, 3 h.p. Quadrant.

Coventry Motor Cycle Club.—J. Browning, 9-h.p. Riley tricar; Victor Riley, 3-h.p. Riley; F. Hulbert, 3-h.p. Triumph; A. Wright, 3-h.p. Triumph.

Essex Beaumont Motor Club.—W. Applebee, 3½-h.p. Rex; C. S. Prentice, 4-h.p. Kelecom; H. G. Bright, 2½-h.p. Bat; A. G. Reynolds, 2½-h.p. Bat; E. Varney, 2½-h.p. Crownfield; W. Gunn, 10-h.p. Lagonda tricar; A. J. Macdonald, 2½-h.p. Vindec; H. C. Horswill, 3½-h.p. Brown; G. E. Revill, Iroquois; J. A. Trussell, 2½-h.p. Gate (De Dion engine); G. Walker, 2½-h.p. Trow.

Ilford and District Motor Club.—R. A. Osman, 3-h.p. Rover; A. Norman, 3½-h.p. Vindec Special; V. Baldwin, 3½-h.p. Royal

Plumstead and District Motor Club.—J. S. Fenn, 2½-h.p. Matchless; T. J. Ellis, 3½-h.p. Matchless; J. Tassell, 3½-h.p. Matchless; H. R. Stamford, 2½-h.p. Matchless; Stanley Webb, 2½-h.p. Kerry; W. R. Henoir, 2½-h.p. Simplex; W. H.

Watts, 2½-h.p. De Dion; A. F. Simms, 2½-h.p. Kerry; T. Parrish, 3½-h.p. Minerva tandem; F. Hills, 3½-h.p. Minerva tandem; C. R. Collier, 4-h.p. Matchless; H. V. Colver, 4-h.p. Matchless.

Consumption Trial.—As a result of the Consumption Trial held at Thames Ditton on September 2nd, a silver medal has been awarded to Mr. H. J. Densham for the machine which accomplished the best performance on a basis of weight and miles per gallon of petrol. Mr. Densham also takes the prize offered to the machine, irrespective of weight, which showed the smallest consumption. Mr. F. W. Applebee also receives a silver medal for the performance of his tri-car.

Tri-Car Trial.—The Auto Cycle Club propose holding a non-stop run for tri-cars about October 21st, subject to there being 10 entries received in good time. The entrance fee is 2 guineas, 1 guinea being returned for each machine which starts. There is no restriction as to the number of machines anyone may enter, and the event is open to private owners. The start will be from Barnet over a distance of about 150 miles.

Irish Motor Cycle Union.—On Saturday, in fine weather, the Dublin Centre of the Union decided the final hill climb of the season. The hill selected proved an admirable venue, being within easy distance of Dublin, and remarkably free from traffic. The change of scene from the ground usually chosen was owing to the damage done to the roads in County Wicklow by the recent storm and its accompanying floods. Saturday's event was well supported, seventeen competitors taking part in the contest. W. H. Meredith did fastest time, C. B. Franklin being second. S. Findlater, on a 1½ Indian, secured first prize in the handicap, made out in the following formula, the lowest points determining the winner:—

Time × Cyl. Cap. The following table gives the results Weight (Rider and Machine) of the various competitors, the hill being four-fifths of a mile from start to finish, the times being taken by Messrs. T. W. Murphy, Colman and Connell:—

Competitor.	Machine and Engine Dimensions.	Weight of Machine and Rider.	Time.	Points.
		lbs.	m. s.	
W. H. Meredith	Triumph (80 × 80) ...	346	1 38½	571
C. B. Franklin ...	F. N. (72½ × 80) ...	289	1 39½	567
J. G. Drury ...	Triumph (78 × 76) ...	290	1 42	638
C. G. H. Lewis ...	F. N. (72½ × 80) ...	255	1 48½	704
S. Findlater ...	Indian (1½) ...	298	1 57½	528
J. A. Armstrong	Swallow (74 × 100) ...	351	2 2½	752
B. Dunphy ...	Minerva (76 × 76) ...	242	2 6	799
C. Flood ...	Minerva (82 × 82) ...	294	2 8½	944
R. Howison ...	F. N. (70 × 80) ...	343	2 8½	594
C. S. Campbell ...	F. N. (4-cyl., 45 × 57) ...	316	2 10	812
G. M. Link ...	Wellington (75 × 80) ...	not known	2 18½	—
H. Mooney ...	F. N. (70 × 80) ...	340	2 23½	620
S. Black ...	Triumph (66 × 70) ...	256	2 25½	678
D. Kennedy ...	Minerva (76 × 76) ...	312	2 36½	771
H. Quinn ...	Triumph (75 × 80) ...	304	2 39½	981
G. Metcalfe ...	Quadrant (66 × 70) ...	266	2 41½	719
J. Mooney ...	F. N. (70 × 80) ...	404	2 43½	648

Sheffield Hill Climb.—A motor cycle hill test was carried through on Saturday at Grindleford by the Sheffield A.C. The timekeepers were Messrs. J. R. Wade and J. E. Evans; umpire, Mr. E. F. Coupe; starting marshals, Messrs. A. F. Fletcher, W. Watts, and J. Barber, and the results were as follows:—

	M. s.
J. Walker, 5-h.p. Devonshire ...	4 36
G. D. Flather, 3½-h.p. White and Popple ...	4 42
F. Donovan, 2½-h.p. De Dion ...	7 11
W. L. Gilder, 2½-h.p. De Dion Tricycle ...	8 27

Hertfordshire Open Hill Climb.—On Saturday last, a hill climb took place under the auspices of the Hertfordshire A.C., on Maple Hill, near Boxmoor, a short but sharp rise constituting a severe test for the motor cycles and also for many cars. Of the 23 entries about 14 started, the fastest time of 35½s. being made by

Godfrey on a 4-h.p. Werner. The event was a handicap, the official times published and handicap placing by class of the only machines which covered the specified course being as follows:—

Class A.—Machines 76 by 76 mm.

Driver and Machine.	m.	s.
1. A. F. Ilsley (2½-h.p. Phoenix)...	0	53½

Class B.—Machines 85 by 85 mm.

3. A. R. Child (2½-h.p. Ormonde) ...	0	40½
1. A. E. Lowe (3-h.p. J.A.P.) ...	0	42½
2. A. Mabon (3½-h.p. Mabon) ...	0	47

Class C.—Machines of any cylinder capacity.

1. O. C. Godfrey (4-h.p. Werner) ...	0	35½
--------------------------------------	---	-----

Class D.—Passenger machines.

2. J. Harwood (8-h.p. Lagonda) ...	1	7½
1. H. Jones (6-h.p. Hardy) ...	1	9½

½-Litre Motor Bicycle Contest.—For the third year the competition over a distance of 100 kiloms. for motor bicycles with a limited cylinder capacity was held on September 19th, 20th, and 21st on the Parc des Princes Track, Paris. The first year the limit was ½ litre. Last year and this year ½ litre was the maximum capacity. Twenty-seven competitors had entered, and as usual the contest was run off in heats and a final, the first two in each heat being entitled to take part in the final. The four heats were run off on the 19th and 20th in the morning and the afternoon, leaving eight machines to compete on the 21st in the final. On the first day Thomas, on an Alcyon machine, created new world's records from 70 kiloms. up to 100, as also for the half hour and the hour, his new times being as follows:—

	Thomas.	Old times.
	h. m. s.	h. m. s.
70 kiloms. ...	0 49 3½	0 49 41½
80 kiloms. ...	0 56 5½	0 56 38½
90 kiloms. ...	1 3 4½	1 3 35½
100 kiloms. ...	1 10 1½	1 10 35½
Half hour ...	42' 657 kiloms.	42' 45 kiloms.
One hour ...	85' 586 kiloms.	84' 700 kiloms.

By this performance Thomas also secured the Hydra Cup for which Cissac so recently, as recorded by us, put up new record times.

On the second day, no new records were created in connection with the ½-litre competition, but during the mid-day interval, Cissac, no doubt spurred on by his previous records being lowered, successfully attempted to further improve upon Thomas's times, he lowering the time for the 100 kilometres from 1h. 10m. 1½s. to 1h. 6m. 46½s., and bettering the distance in the hour by close upon 4½ kilometres. The details of Cissac's records we publish below, but a dispute has arisen as to Cissac being entitled to the Hydra Cup, as it is held that one of the rules requires 24 hours notice to be given of intention to compete for this Cup, and that Cissac did not give this necessary notice.

In the final Thomas secured the premier position against the other seven riders, his machine being an Alcyon with a Buchet motor, whilst the second place was secured by Anzani on a similar machine, a Magali bicycle, also with a Buchet motor, taking the third place. The times accomplished, which are a considerable improvement on the previous year's speeds, must also be regarded as exceptionally good in view of the fact that eight machines were competing on the track at the same time, and it was necessary to pass and re-pass upon several occasions. Anzani, who was travelling splendidly throughout, would probably have equalled Thomas's Alcyon except for the fact that he had to replace a sparking plug, which occupied him 2 mins. The times accomplished in the final were not as good as in the earlier stages. The following were the results of the final:—

The awards for regular running, of teams notified beforehand, were as follows:—

1. Alcyon. 3 machines qualified, 3 in the final.
2. Lurquin-Coudert. 3 machines qualified, 1 in the final.
3. Albatros. 2 machines qualified.

For the "Regularity" awards a maximum time of 2½ hours was specified for covering the 100 kiloms., the best times determining the placing.

By way of comparison of times, *L'Auto* has drawn up the following table showing the best performances for 1905 and the best performances for 1904 ranged in their order of merit:—

	h. m. s.		h. m. s.
Thomas (1905) ...	1 10 34½	Billot (1905) ...	1 21 52½
Anzani (1905) ...	1 11 40½	Méline (1904) ...	1 24 48½
Nazo (1905) ...	1 16 53½	Griet (1904) ...	1 26 7½
Anzani (1904) ...	1 18 37½	Champoiseau (1904) ...	1 26 43½
Giorgis (1904) ...	1 19 58½	Armbruster (1905) ...	1 26 57½
Capeaumont (1905) ...	1 21 50½		

New Motor Bicycle Record.—Cissac, on Wednesday last week, successfully lowered his own and Guipponi's records for ½ litre motor bicycles, and at the same time bettered the new times made the previous day by Thomas on his Alcyon machine, in connection with the ½ litre "Criterium," which was run off on the Parc des Princes track, Paris, and particulars of which we give above. Cissac, whose machine was a Peugeot, was running in splendid style, and commenced beating all records from 10 up to 100 kiloms., including the half hour and the hour distances. His time for the 100 kiloms. was 1h. 6m. 46½s., beating Thomas's previous time by over 3 minutes. The new record times put up by Cissac was as follows:—

Kiloms.	h. m. s.	kiloms.	h. m. s.
10 ...	0 6 41½	60 ...	0 40 19
20 ...	0 13 18½	70 ...	0 46 41½
30 ...	0 19 58	80 ...	0 53 23½
40 ...	0 26 37	90 ...	1 53 4½
50 ...	0 33 19	100 ...	1 6 46½
Half hour	45' 40 kiloms.	
One hour	89' 895 kiloms.	

Indian Motor Cycle Trials.—A successful trial for motor cycles was last month concluded in India between Poona and Satara and back, a distance of 140 miles, this being the same route as the one selected for the Aga Khan Cup motor car trials on the 11th of this month. Hitherto motor cycles have not been particularly in favour in India, but apparently recently they have been more sought-after and no doubt the present trials will give a special impetus to their introduction into the country. The trial was a reliability one and not one of speed, the route including the well-known Katraj and Khandalla Ghats. The ascent of these well known mountains is at times not only difficult but distinctly dangerous, the roads are in numberless places spread with loose metalling, and at points gradients of 1 in 10 and steeper have to be surmounted. On one side of the road is the rising hill while on the other the rider is faced with a precipice. The road is of this character for many miles, and at places there is practically no room even to pass. The fact that no accidents of any sort resulted may be regarded as a matter for considerable congratulation by the organisers, the run being mainly under the control of Mr. Pat Stewart, who acted as secretary, Mr. F. H. Vincent being the starter. The conditions governing the trial provided for machines up to 3½-h.p., and a maximum time of 11 hours for covering the distance, including controls. All riders timed within the 11 hours were entitled to run for the Aga Shah Trophy. This trophy was run off on the same evening, and consisted of a speed trial and hill climb to the Katraj tunnel and back. Altogether 15 entries were received for the main

Place.	Machine and Driver.	Time.	Motor.	Bore.	Stroke.	Carburettor.	Tyre.
		h. m. s.					
1	Alcyon I. (Thomas) ...	1 10 34½	Buchet ...	76	73	Longuemare ...	Dunlop
2	Alcyon II. (Anzani) ...	1 11 40	Buchet ...	76	72	Longuemare ...	Dunlop
3	Magali (Nazo) ...	1 16 53½	Buchet ...	76	72·8	Vaurs ...	Dunlop
4	Lurquin-Coudert (Capeaumont) ...	1 21 50½	Lurq.-Coud. ...	76	70	Longuemare ...	Dunlop
5	Alcyon III. (Billot) ...	1 21 52	Buchet ...	76	72·5	Longuemare ...	Dunlop
6	Buchet (Armbruster) ...	1 26 57½	Buchet ...	76	73	Malézieux ...	Dunlop
7	Chanon (Villemain) ...	1 30 51	Villemain ...	74	77	Longuemare ...	Dunlop
8	Quentin (Contant) ...	1 32 53½	Quentin ...	76	73	Malézieux ...	Dunlop

event; all the machines, with the exception of one, were ridden by their owners. The competitors were sent off at minute intervals, and the usual eliminations took place, owing chiefly to broken valves and tyres. The competitors who got through in the specified time allowed were as follows:—

Machine and Driver.	Net Time.
	h. m.
2½-h.p. Royal Riley (Mr. Pat Stewart) ...	5 11
2½-h.p. Peugeot (Lieut. Jenkins) ...	6 5
2½-h.p. Matchless (Lieut. Burmester) ...	6 15
3½-h.p. Chase (Mr. Nigel-Jones) ...	6 46
3½-h.p. Rex (Mr. F. Pooley)...	7 27
2½-h.p. Hobart (Mr. R. Mody) ...	7 56

CLUBS AND ASSOCIATIONS.

THE Society of Motor Manufacturers and Traders is continuing to receive daily returns from firms in the motor trade, for the purpose of laying statistics before the Royal Commission on the Motor Car Acts, which commences its sittings on October 16th. In addition to the firms whose names have already been published, the following have sent in returns: Alford and Alder, Ariel Motor Company, Limited, Albany Manufacturing Company, Limited, Burlington Carriage Company, Limited, Albany Engineering Company, Coventry Motor Fittings Company, Cunliffe and Croom, Limited, Cann, Limited, Dicks and Son, De Dion Bouton, Limited, Charles Foot and Son, Thomas W. Garside (Ambleside), Samuel Gordon (Bolton), Humber, Limited, J. B. Huxley and Co., Imperial Tyre and Rubber Company, Limited, Kreiger Electric Carriage Syndicate, Lowe, Bevan and Co., Legros and Knowles, Limited, McNeil, Hutchinson and Co., Limited, Murchie and Picken, H. P. Moore and Sons, Orleans Motor Company, Limited, Putney Motor Company, Limited, John Roberts (Manchester), C. S. Rolls and Co., Rice Bros. (Horsham), Sirdar Rubber Company, Limited, Sunbeam Motor Car Company, G. Saxon (Eastbourne), Thomas Tallows (Manchester), Victoria Carriage Works, Limited, White and Poppe, Limited, William Wilson and Son, Limited, Alnwick Motor Garage and Cycle Company, Limited, W. H. M. Burgess (London), W. J. Binks and Co., Bolton Motor Company, Limited, Botwood and Egerton, John Croall and Sons, Limited, A. Deacon, and Son (Llandudno), James Davers (Broseley), Free-Lance Motor and Engineering Company, H. K. Hales (Burslem), Holland Bros. (Boston), J. D. Hodgson (Newcastle-on-Tyne), S. E. Maund (Craven Arms), Mengies Bros. (Bridge of Allen), Northern Motor Company (Belfast), Pemsel and Wilson (Hemel Hempstead), A. Pellant (London), Rennie and Prosser, Limited (Glasgow), A. A. Speannan (Braintree), Buchanan Shiell (Perth), M. H. Tilley and Son (Dorchester), Charles T. Tycett (Burslem). Before the Commission sits the information obtained in the returns

Mr. Mody, who rode a Hobart machine, managed to find the customary dog with unpleasant consequences to himself, but, in spite of his mishap, he was able to be amongst those who completed the run in good time. Several enthusiasts accompanied the competitors on their cars.

The first five home were eligible for contesting the Agar Shah Rookh Shah Cup. Only three, however, started, viz., Lieut. Burmester, Lieut. Jenkins, and Mr. Pat Stewart. The first-named was early out of it owing to ignition troubles, and after a close race Mr. Pat Stewart was declared winner with 1m. 22s. to spare.

International Cup for Motor Bicycles.—Modifications are proposed in Austria, that in future years the weight of the machines should be fixed without tyres.

will be digested and tabulated by a noted firm of accountants, due respect being paid to secrecy so that no firm's business will be disclosed, and the result will be laid before the Royal Commission by Mr. T. F. Woodfine, on behalf of the Society.

THE Yorkshire Automobile Club, in view of the present public feeling, has deemed it advisable not to hold a hill-climbing competition this year, but to support by every means in its power the endeavour to stem the prejudice that exists on the part of magistrates and the police against motorists, and, with this end in view, the Club is assisting the Motor Union in obtaining all the statistical information it possibly can for the Royal Commission on the working of the Motor Car Acts, with a view of furthering this object.

COMMERCIAL POINTS.

Chénard Walcker Cars.—The sole agency for England and Wales for these well-known cars has been secured by Messrs. Miller, Baker and Oakley, who have formed a company, under the managing directorship of Mr. Godfrey Oakley, which has been registered as "Chénard Walcker Motors, Limited," with offices, show-rooms, and garage in Long Acre. We understand that Messrs. Chénard Walcker and Co., of Paris, are manufacturing an entirely new model for the English market. The chassis, which will be fitted with a 16-h.p. four-cylinder engine, having both battery and high-tension magneto ignition, will be one of the features of the next Olympia Show.

Motor 'Bus Tyres.—Referring to a paragraph which appeared in our issue of the 16th inst., on this subject, the Sirdar Rubber Company draw our attention to the fact that the 11,000 miles' service performed by a set of their tyres, on the front wheels of one of the London General Omnibus Company's vehicles, is a clear gain of 1,000 miles to the 'bus company, since the price of the tyres—which are guaranteed not to cost more than 2d. per mile—is based on the guarantee that they will run 10,000 miles.

THE Panhard and Levassor travelling workshop will be at the Wellington Hotel, Harrogate, from the 30th of the present month.

THE new works of the Motor Manufacturing Company, Limited, taken by the Receiver and Manager for the Company, are situated at Parkside, to which works the M.M.C. business is now being removed.

MR. WERNER LAURIE will shortly publish a book for the motorist, entitled, "My Motor Log Book." In the main, it is a log-book for recording dates, runs, &c., but summaries are given on such points as the 1903 Act, index marks, &c.

The first of the 24-30-h.p. four-cylinder De Dion cars to arrive in this country. This very roomy car has seating accommodation for seven persons, and is fitted with double Cape-cart hood, celluloid roll-up wind-shield for protecting passengers on the front seat, and a separate wind-shield on the back of the front seat to protect passengers in the rear of the car.

MOTOR BOATING.

The British Motor Boat Club.—The meeting which was announced for Thursday, Friday, and Saturday this week, promised to make a pleasant and satisfactory wind-up to the motor boating season. In addition to the races already announced for to-day, Saturday, a flying mile championship is arranged to be held, a gold medal being given for the fastest record. For this Brooke I., Napier, and Napier II. are entered, whilst for the general classes on the first two days, in addition to these three well-known racing craft, the following boats were down to take part:—Pallas, Elgiva, Stirling, Fiat, Baby II., St. Helena, Hummono, Comet, and H.H. the Sultan of Johore's boat.

Lake Maggiore Motor Boat Meeting.—On the 18th instant the meeting on this Italian lake was held, but only a very meagre entry list resulted. A 20-kilometre course was buoyed out, and the racing craft went round this five times, making a total of 100 kilometres. The results were:—1 Antoinette III., 2h. 30m. 3½s.; 2 New Trèfle, 2h. 37m. 2¼s. In the cruiser class (over 60 kilometres), the results were:—1 Delahaye IV., 1h. 54m. 40s.; 2 Mendelssohn, 2h. 40m. 31s. Subsequently a handicap race was run over a distance of 40 kilometres in very unfortunate weather, the rain coming down in a deluge through the whole race. In this the placing of the competitors was:—1 Delahaye IV. (22 min. start), average speed 32.2 k.p.h.; 2 Mendelssohn (52 min.), speed 22.4 k.p.h.; 3 New Trèfle (9 min.), speed 35.3 k.p.h. Further racing was abandoned in consequence of an accident to one of the boats on the lake.

THE motor boat races this year organised by *L'Auto*, and held in the Maisons Lafitte Basin for the third year in succession, will take place on October 22nd.

THREE motor racing boats engined with Mercedes motors are to be built for next year's Monaco races. They will be constructed on different lines to the ordinary Mercedes car engines, and Herr Jellineck states that they are to have eight cylinders, developing 240-h.p. at 800 revs., the weight will exceed 1,000 kilogs., and a speed of over 34 miles an hour is expected to be attained. Two of the hulls are to be built in France, and one in Germany.

A FINE example of what the motor boat can do in an emergency was provided by the accident that happened to the Lord Lieutenant of Ireland when competing in a yacht race on Thursday last on Lough Erne. His Excellency, who is a keen yachtsman, was sailing in a light yacht competition during very rough weather, having Capt. the Hon. G. Crichton and Lady Mabel Crichton as passengers. A sudden squall capsized the yacht which Lord Dudley was sailing, and he and his two passengers were left struggling in the water, a good

half mile from shore. Under ordinary circumstances they would probably have been in considerable difficulty, had they had to depend on ordinary rowing boats to come to their assistance, but fortunately Lord Dudley's motor launch was in attendance, and went full speed to the rescue, all the occupants of the boat being quickly transferred to *terra firma*. The Lord Lieutenant and Lady Mabel Crichton are none the worse for their immersion, though Capt. Crichton suffered an injury in attempting to free some of the rigging which the squall had brought down on deck.

The New Arrol-Johnston Car Co.—Originally the manufacturers of the victorious car in the Tourist Trophy Race conducted their business under the title of the "Mo-Car Syndicate," but for some time past the title of the company manufacturing this car has been the Arrol-Johnston Car Co., Limited. In order to allow their work to be conducted in a thoroughly efficient manner, and to effectively cope with the influx of orders, the company have increased their capital to £100,000. For the present the output of the works will consist of two distinct types of tourist vehicles, the smaller of which will have the horizontal type of engine, similar to that on the winning T.T. car, and the larger will be fitted with a four-cylinder vertical engine, capable of developing 24-h.p. The 12-h.p. car will probably be placed on the market at about £410, while the 24-h.p. car will be priced at about £750. In addition to the above the firm will also manufacture 12-h.p. and 24-h.p. commercial vehicles, and, in so doing, they will be swelling the now long list of high-class British firms who are devoting their serious attention to this important side of the industry.

A well-designed 24-h.p. standard char-à-banc, which has recently been supplied to the Northern Counties Committee of the Midland Railway by John I. Thornycroft and Co., Limited, for use in the North of Ireland. This machine has been adopted by the Company after a considerable trial, the only modification required by Mr. Malcolm, the locomotive engineer, being a slight raising of the petrol tank to meet local conditions, as when surmounting the exceptionally severe gradients met with on the road the vehicle is to serve, the level of the petrol in the tank was below that of the carburettor. On its home trials, the car was easily taken up hills of 1 in 7 with a full load, the petrol tank under those conditions being found to give an ample head of petrol in its usual position.

TOURIST TROPHY RACE.—The 14-h.p. Vinot Car which secured third place in the recent great race. Average speed 33.4 m.p.h., with a fuel consumption of 23.3 miles to the gallon.

AERONAUTICS.

Farcical Proposals.—The modesty of some people is truly magnificent, and a wonderful modesty is evidently the leading characteristic of a certain Mr. Edgar Wilson who, as we have chronicled, first of all attempted to take a header from Westminster Bridge with a flying-machine (stopped by the police), and subsequently took headers into the lake at Wembley Park. It is not clear that he even flew, in the true sense of the word, a single yard, though his machine once, at any rate, careered from the platform to the lake while he remained in suspense amid a limbo of ropes, from which he was subsequently extricated not without difficulty. There is virtue in the old proverb, "Who ventures wins," and Mr. Wilson is so satisfied with his Wembley Park experiments that he now proposes to attempt reaching the North Pole in an airship, which, needless to say, is to resemble Jules Verne's "Clipper-of-the-Clouds." It is to be 100 feet long and 14 feet wide, and Mr. Wilson "anticipates" being able to proceed at a speed approaching fifty miles an hour. With the modesty to which we have referred at the commencement of this paragraph, Mr. Wilson has approached the Admiralty, requesting that the Government should assist him by dispatching a cruiser with a wireless telegraph apparatus to follow his airship. It is obvious that the cruiser can hardly be expected to reach the Pole by many hundred miles, to say nothing of the question as to whether the Government will be inclined to dedicate a cruiser to the effort. Surely it would be better for Mr. Wilson to apply to the Russian Government, who might place their celebrated St. Petersburg ice-breaker at his disposal, which might be expected, at any rate, to get a little further through the Polar ice.

Strangely enough no notice has been taken of Mr. Wilson's project by the International Meeting of Polar Explorers, which has recently assembled in Belgium. He does not figure at all among that select band of discoverers.

The International Meeting mentioned above has been convened by the King of the Belgians, and includes the veteran and world-famous Professor Nordenskiöld and Messrs. Bruce and Shackleton. The result of their deliberations is to be presented to the Mons Congress, and aeronauts will certainly be interested to learn to what extent, if any, the navigable airship is likely to be put forward as an effective means for Polar exploration.

WE are able to provide some further particulars of the strange airship with oars which has excited so much attention at Los Angeles, in California. The machine in question consists of a gas bag of practically the same shape, and about the same size, as that of M. Santos Dumont's No. 9. Underneath it is slung a very light framework. Two oars with huge blades, made of a fabric stretched on a bamboo framework, are provided, and the occupant rows with these (presumably feathering carefully) as in an ordinary row-boat. It is said that a speed of as much as six miles an hour has been attained, but, needless to say, the arrangement, though entertaining, is incapable of successfully contending with anything serious in the nature of a wind.

THE new motor omnibuses, both single and double-deckers, which are being placed on the London streets by the London Power Omnibus Company, Limited., are to be known as "The Pioneers."

LONDON TO NEUCHÂTEL.—The Martini Car, which was brought over by Mr. Martini to run in the "Graphic" Race in the Isle of Man, being shipped back from Dover on its return journey from London to Neuchâtel. Mr. Martini, who was extremely disappointed at not being able to take part in the race, owing to its postponement through the bad weather, drove the car immediately afterwards back to Neuchâtel, accompanied by Mr. Douglas Miller, who appears in the photograph standing in front of the car on the left, Mr. Martini being in his seat at the steering wheel.

How to Drive.—Mr. S. F. Edge certainly deserves the title of the "Admirable Crichton" of the automobile world, for he manages the pen of the ready writer (as his articles in numerous reviews to which we have from time to time referred, most adequately testify) with the same exquisite ease and precision with which he controls the steering wheel of his car. These remarks are called forth by the very interesting and suggestive article which he has recently contributed on the subject of motor car driving to the columns of the *Daily Mail*. In this article Mr. Edge describes with rare skill, and naturally with the knowledge of the expert, the essential differences between racing and ordinary tourist driving. The very contrast of the difference in methods brings out with special force the value of a real apprenticeship to the art. It is to be hoped that every car driver will read this excellent *résumé* of the main elements involved in high class driving, and thoroughly lay the conclusions to heart. The result will unquestionably be a diminution in the already small number of motor car accidents.

THE solitudes of Mount St. Bernard, where dwell the celebrated monks and their no less celebrated dogs, are being invaded by the rhythmic throb of the motor lurry. A machine of this description, capable of dealing with a load of 4,000 kilogs., is being introduced for the purpose of transporting supplies from Martigny up to the famous hospice. The first climb of the lurry was effectively made recently. It presented a somewhat entertaining appearance, for, with a view to convincing the horses of the district that the machine was harmless, a representative of *Dobbin communis* was harnessed in front of it, forming a sort of animal figurehead. The tremendous climb was successfully accomplished in a single day.

WE are glad to find that some magistrates are disinclined to swallow any fare which the police put before them, at any rate in ordinary cases. Mr. Atkinson, the stipendiary magistrate of Leeds, was recently so angry with the contradictory, untrustworthy, and obviously lying evidence tendered by policemen in support of summonses for assault that he dismissed both of them, remarking that he refused to act on "false sworn testimony in this or any other case." Presumably the police are becoming so demoralised by the tactics and hard swearing that they have had to adopt to ingratiate themselves with the anti-motor "great unpaid" that they are carrying the same lack of principle into ordinary everyday cases. Not that all magistrates are alike, as we have often pointed out, and gradually a more liberal and humane spirit is disseminating itself among our country justices. Already several of them have protested against antimotorist tactics as frequently adopted, and to the names of these elect we have to add that of the Chairman of the East Riding Bench of Yorkshire, who, at a sitting of that Bench recently, expressed his strong disapproval of the laying of police traps to test the speed of cars on open country roads, adding that the police would be much better employed in detecting reckless driving through village streets.

THE London and North-Western Railway officials have just completed a tour of the Anglesey roads, with the object of arranging for a service of motor cars in connection with their system.

THE Great Western Railway Company have now about eighty motor omnibuses running in connection with their system, and have found them in every way successful, and an enormous help as feeders in bringing passengers and goods to the railway. The chairman of the Glasgow and South Western Railway, at the recent general meeting held in Glasgow, announced that orders had been given out by the directors for a number of passenger road motors, which were to be put on as feeders to their line at the earliest possible moment.

AMID the general extension of classes at the Battersea Polytechnic, we are pleased to note that those which refer to motor-car engineering are being expanded and brought up to date, while a course of evening lectures, followed by practical work in the design, construction, and working of petrol and other motors, has been arranged for. The Battersea Polytechnic is making a speciality of educating motor-car engineers as apart from chauffeurs, though this latter field of activity is not being neglected, as many as 200 students having passed through the course for chauffeurs since September last.

EVERY English automobilist, and indeed every Englishman, will be sorry to learn of the unfortunate accident which recently occurred to the ex-French Minister of Foreign Affairs, M. Delcassé. M. Delcassé was motoring through his native department of Ariège, when, on a very bad bit of road near Elbouch, the car skidded and collided with a tree. M. Delcassé, M. Clarac, and the mechanic, were flung out and fell into a ditch full of mud, which was unpleasant, but saved them from injury. M. Delcassé's foreign policy was always so consistently friendly to Great Britain that everyone in this country will be delighted to learn that he thus escaped serious injury.

A specimen of a luxuriously fitted 22-28-h.p. Crossley touring car which has recently been supplied to Mr. George Myers, of Birmingham, and was built specially for touring on the Continent.

NEW COMPANIES REGISTERED.

[Taking powers to manufacture or deal in motors, motor cars, or accessories, either as their principal or part of their objects.]

British Motor and Engineering Company (Limited).—Capital, £2,000 in 1,000 ordinary shares of £1 each, and 20,000 deferred shares of 1s. each.

Engineering and Motor Tools (Crocker-Barnes Patents) (Limited), 31, North John Street, Liverpool.—Capital, £25,000 in £1 shares. Object, to acquire the patents, &c., of the Crocker-Barnes Tools Syndicate, Limited, carried on at 37, Westmoreland Street, Liverpool. First directors, W. R. Biddell, E. C. Harvey, E. A. Mackenzie, C. Williams, and S. H. Crocker.

Motor World Publishing Company (Limited).—Capital, £4,000 divided into 1,500 ordinary shares and 2,500 preference shares of £1 each. Object, to take over the *Motor World* and *Industrial Vehicle Review* (Scotch Company).

Drivers' Certificates.—For the purpose of enabling drivers throughout the various parts of the country to obtain Drivers' Certificates and Certificates of Mechanical Efficiency, under the rules of the Automobile Club, with as little inconvenience to themselves as possible, special arrangements have been made to hold examinations, as follows:—

Coventry and district, Monday, October 16th.
Birmingham and district, Tuesday, October 17th.
Manchester and Liverpool district, Wednesday, October 18th.
Sheffield, Huddersfield, and Leeds district, Thursday, October 19th.
Leicester, Nottingham, and Derby district, Friday, October 20th.
Oxford, Reading, and Swindon district, Tuesday, October 24th.
Bristol, Bath, Gloucester, Cheltenham, and Taunton, Oct. 25th.
Exeter and North Devon district, Thursday, October 26th.
Plymouth, South Devon, and Cornwall, Friday, October 27th.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E., Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

189. 4th January, 1905. Improvement in and relating to Oil Engines. Messrs. Bellis and Morcom, Limited, and Alexander Jute, Ledsam Street Works, Birmingham. This invention is intended to promote the attainment by the heavier oils of a spheroidal condition when exposed to a hot vaporising surface, and thus avoid the acquirement of a decomposing temperature by any of its molecules whilst in the liquid condition. The method by which this effect is obtained is by incorporating with the heavy oil another liquid which is ready to assume the spheroidal condition and form a buoyant atmosphere which will suspend the petroleum particle out of contact with the hot plate, but subjected to a sufficiently high temperature to effect its entire evaporation. In the case of water being used for this purpose an emulsion is formed of petroleum and water by an intimately mixing contrivance of the egg-beating type. Such an emulsion does not readily separate into its components, and when it is fed to the vaporiser of an oil engine, the added water will operate as a sustaining and isolating agent for the suspended oil. On leaving the emulsifier the mixture should pass to the vaporiser, where, during the interval between the admission operation of two successive cycles, it is subjected to heat, and by the buoyancy of the water vapour the petroleum particles are sustained out of contact with metal which is hot enough to effect its decomposition. There is one figure. *a* is the tank con-

retained against its seat by the action of a light spring, *m*. Leading to the chamber, *k*, there is also provided a passage, *n*, from the atmosphere beneath the valve, *m*, to the vaporising chamber, *a*, from which a mixture of air and vapour is drawn into the motor cylinder through the opening, *o*, on the suction stroke of the motor. During the period between two suction strokes, the emulsion will collect on the surface of the valve, *m*, and partial vaporisation will take place there, and when the valve opens, by the partial vacuum produced below, the emulsion will be carried by the entering air as a finely-divided conical sheet of spray. By forming an upturned edge at the periphery of the valve the spray condition will be promoted.—September 6th, 1905.

19867. 15th September, 1904. Novel or Improved Means for Use in Propelling Ships, Boats, and other Craft by Internal Combustion Engines. The Wolseley Tool and Motor Car Co., Limited, and Herbert Austin, Adderley Park, Birmingham. The object of this invention is to facilitate the starting of a main central propeller, or the engines of main twin propellers, and to adapt means whereby auxiliary twin propellers may be utilised in driving

E E, are first started, while the main engine shaft, A, is out of clutch with the shaft, *a*, and consequently free in relation to the gear wheel, H, and then the shaft, A, is clutched to the shaft, *a*, and is consequently in motion by the auxiliary engines. To utilise the auxiliary engines to the best advantage in starting the main engine, they should be out of gear with the auxiliary propeller shafts, and they may be used in combination with the main engine simply for driving the main shaft when it is desired to transmit the maximum power through the shaft. The auxiliary engines may be used also in driving the auxiliary twin propeller shaft, D D, while the main propeller shaft is driven by the main engine, or may drive such auxiliary twin propeller shafts while the main engine is standing, for the purpose of reversing the ship or of keeping up steerage-way or otherwise. A dynamo-electric machine, K, having its axis in alignment with the shaft, *a*, on which is the wheel, H, capable of being engaged with and disengaged from the shaft, *a*, at will, such as through the medium of a friction clutch, L, may be driven by the auxiliary engines E E, or by either of them, for the purpose of charging accumulators, or for electric lighting, or for driving bilge pumps or other mechanism at some distance away in the ship, and this dynamo may be utilised if desired as an electric motor to start the auxiliary engines.—September 6th, 1905.

taining a supply of the oil. It flows to a rotary pump, *b*, by the pipe, *c*, past a gauze screen, *a*, which is interposed to arrest solid impurities, a hand-regulated valve, *d*, and an automatically-controlled valve, *e*, the area of opening through which may be regulated by the speed governor of the engine. When the speed limit is reached, an arm, *f*, is caused to press on the end of the spindle of the valve, *e*, and close it more or less completely against the force of a spring, *g*. The water for mixing with the oil is shown as being taken from the water-jacket at the upper end of the motor cylinder, *c*. On its way to the rotary pump by the pipe, *f*, the water also passes an automatically-controlled valve, *g*, constructed and arranged similarly to the valve, *e*. From the pump, *b*, the mixed fluid flows through the pipe, *h*, to an apparatus, *i*, wherein, by violent agitation, the mixed fluid is beaten into fine particles, which, being interspaced more or less perfectly between each other, retain their divided conditions for a sufficiently long period to serve the purpose. A non-return valve, *k*, and regulating taps, *l* and *m*, may be fitted with advantage. From *i* the emulsion is forced through the pipe, *j*, into a chamber, *k*, above the valve, *m*, which is normally

or in reversing or in steering, as required, or to adapt means to drive a single auxiliary propeller, having its axis somewhat to the side of the main propeller, either forwards or reverse as desired. There are three figures. Fig. 1 is a plain view of the invention as applied to a main central propeller. A is the shaft of an internal combustion engine, which drives the central main propeller. B B are the cylinders. D D are the shafts of auxiliary twin propellers, which pass along at opposite sides of the axis of the main shaft, A. E E are auxiliary internal combustion engines, which are geared with the auxiliary propeller shafts through gear boxes, F F, in such a manner that each of them will drive the corresponding shaft forwards or reverse as desired, or be thrown out of gear. On each auxiliary engine shaft, *e*, is mounted a pinion, G, and on a shaft, *a*, which is in alignment with the shaft, A, is a gear wheel, H, with which both the pinions, G, are constantly in mesh. The shaft, A, is normally in clutch with the shaft, *a*, through a friction clutch, J, and the interlocking of the pinions, G, with their shafts, *e*, may if desired be by means of clutches, so as to enable either of them to be thrown out of clutch. To start the main engine, the auxiliary engines,

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—Officers and men of the repair train of the Mechanical Transport Army Service Corps. Mechanical transport in the army has made exceptionally rapid strides under the influence of Col. F. T. Clayton, C.B.,—Assistant Director of Transport at the War Office, but it was not until the recent military manoeuvres that any organised base, for the efficient repair of the actual machines used in transport, was introduced. The repair train, as this section is called, consists of several travelling workshops which have been equipped under the supervision of Major W. E. Donohue—Chief Inspector of Mechanical Transport—who together with his staff is seen in the above group.

THE AUTOMOTOR JOURNAL.

Telegraphic address: Truditur, London. Telephone: 1828 Gerrard.

SUBSCRIPTION RATES.

THE AUTOMOTOR JOURNAL will be forwarded, post free, to any part of the world at the following rates:—

PASSING EVENTS.

Mechanical Transport and the Army.

IN another column we give an account of a recent development in connection with mechanical transport in the Army. The British military authorities have been steadily developing the mechanical transport branch of the service till it has now reached a very high degree of efficiency, and they have this year made a departure which distinguishes the present position of that branch of the Service in a very marked way from what it has been in the past. Hitherto, the mechanical transport department has been a branch which on active service was condemned to operate practically without a base, and when repairs were necessary, difficulties were naturally liable to be encountered. Now the progressive spirit of the officers responsible for its organisation has provided it with the most effective base possible—a base that is itself of a mobile character. We refer to the repair train—mobilised for the first time at the recent manoeuvres—which now forms an integral part of this branch of the service, and which renders it, in practically all respects, self-supporting and independent of circumstances. The organisation of this repair train is a striking proof of enterprise and progress, and it is of the most favourable augury for the progress which we may expect this essential department of military efficiency to make in their hands.

More Power for Local Bodies—Perhaps?

THE people who love not the automobile are particularly anxious to increase what are termed "the powers of local bodies." Such a proposal has been put forward by the Paddington Borough Council, who are anxious that the next Motor Car Act should have this effect, and the Highways Protection League, which might be termed the Automobile Suppression Institution, is notoriously of the same way of thinking. The County Councils and the Borough Councils, which are the only local bodies under the Motor Car Acts (although District Councils and even Parish Councils think they are), have, with a few notable exceptions, been the regular mouthpieces of anti-automobile-monomania. As their members are mostly small tradesmen or farmers, with either squires or brewers as chairmen, this is not greatly to be wondered at, and no doubt the other people who would like to improve the automobile off the face of the earth, are quite wise in proposing to increase the powers of such provincially-minded representative assemblies. We are frequently having instances of what local bodies would do if they had all the powers they would like to have, and if they could regulate automobile traffic as they would like to do. The districts in which a speed of more than 10 miles an hour would be permitted would then be few and far between. The correctness of these observations is well illustrated in the case of the Bradford Town Council, one of whose prominent members has suggested that the best method of limiting the speed of motor cars is to empower the local registering authorities to refuse the registration of cars unless they are fitted with a speed and mileage recorder, and are incapable of travelling on a "level plane" at more than 20 miles an hour. This member of the Bradford Corporation objects to "the only mode in use at present for checking the speed, *i.e.*, having a given distance carefully measured and policemen stationed there with stop-watches," as he thinks this is far from satisfactory and has the *appearance* of setting a trap. We are fully in agreement with the Bradford Town Councillor on this point. So widely indeed has his view been generally accepted, that the expression, "police-trap," has in some unregenerate circles been applied to arrangements of this description.

Testimony to the Importance of the Industry.

GRADUALLY, automobile engineers have been taking more and more advantage of the most recent improvements in metallurgy, though it has after all been but gradually that they have recognised what the up-to-date steel maker can do for them. Official recognition has now been bestowed on automobilism by the Iron and Steel Institute by the reading at this year's meeting of that institution of a paper by M. Leon Guillet on "Steel used for Motor Car Construction in France." All great industries react upon one another, and the demand for the highest possible class of shock-resisting material which modern automobilism has created, has already produced a considerable effect on the manufacture of the higher grades of steel.

Other papers read at the Sheffield meeting cannot fail to be of interest to automobile engineers. Among them we would particularly refer to the paper by Messrs. Richards and Stead, on "The Application of the Re-heating Treatment to Ordinary Steel Castings." The marvellous effects produced by this process on forged steel were described by us when this method of treatment was first introduced, and it now appears that a similar great

improvement can be effected in the structure of ordinary steel castings. Mild-steel castings are employed to an ever-increasing extent in automobile construction, and this extension of the Stead process is certain, therefore, to benefit automobile manufacture.

Clearing for Action.

THE day when the great campaign will open is now rapidly approaching. On the 16th of the present month the Royal Commission will commence its sittings, and no one can entertain the slightest doubt that on the result of its deliberations the future of the motor car industry in these Islands will very largely depend, at any rate for some, and probably for many, years. The Motor Car Commission may be to a large extent regarded as a Bench of judges and legislators combined, who are entrusted with the weighty duty of deciding what the future of the greatest English industry of recent growth shall be. We have frequently urged upon the automobile world the importance that attaches to having the case of the motorist and automobile manufacturer adequately placed before the Commission. It is satisfactory, therefore, to learn that the forces on our side are already shaping well, due to their being most adequately and skilfully marshalled for the opening of the campaign.

A Splendid Harvest of Evidence.

MR. REES JEFFREYS, under the ægis of the Joint Committee of the A.C.G.B.I. and the Motor Union, has been working with the most admirable fervour and intensity to get together exhaustive statistics and data in support of the motorists' case, and the mass of information which has been collected and which will form the basis of the evidence they will put before the Royal Commission has, we believe, exceeded all anticipations. Special offices have had to be secured and a considerable staff of clerks has had to be specially engaged for the purpose of dealing with it, and they have been compelled to work long hours and at high pressure. Evidence in favour of legislation that will promote the development of the automobile movement has come in, not only voluminously, but from *unexpected* sources, a large amount being furnished, contrary, perhaps, to anticipation, by people who are themselves non-motorists, including medical men who have had to give evidence in cases of accident, and whose good word for the automobile cannot fail to make a profound impression upon the Royal Commission.

The Society of Motor Manufacturers and Traders, too, have left no stone unturned and no nerve unstrained to provide the Commission with the statistics needed to enable them to form an adequate opinion of the present extent of the great development and the imposing dimensions to which the automobile manufacturer of Great Britain has already attained. For this purpose, the Society have taken a census of all the manufacturers in the kingdom, providing information regarding the number of hands employed, the amount of machinery they use, and other statistics of a similar kind. To this census, no less than 126 different firms of automobile manufacturers have already replied.

The subscriptions of both the society as a body and of their individual members and of private individuals, to the war-chest of the Joint Committee of the A.C.G.B.I. and the Motor Union, have been numerous and munificent. In fact, that fund now stands at the imposing

figure of over £2,900, and will probably have been further substantially increased by the time this number of the Journal is in the hands of our readers.

The energy of both these great bodies, and the splendid way in which they have been supported, not only by private automobile owners and manufacturers, but by unprejudiced non-motorists who recognise what the future is to the automobile industry, and its development will contribute to the general well-being of the country, has been most encouraging, and of the happiest augury for the ultimate result.

Dealers' Marks—A Satisfactory Decision.

CONTEMPORANEOUSLY with their admirable work with reference to the Royal Commission, the Society of Manufacturers have been giving very careful consideration to the question of dealers' marks, and to the preposterous decisions that have been given under this unsatisfactory section of the Act by a number of magistrates. Hitherto decisions on this point have nearly all gone one way, but we are now glad to be able to chronicle an important case which will, we trust, be the forerunner of a generally more sensible attitude on the part of magistrates. Mr. C. E. Hutchin, an employee of Messrs. Thornycroft and Co., who was testing a chassis with a temporary body attached to it, the car being provided with a trader's red number, was at the West London Police Court summoned in the usual style for driving an unregistered car. After a tough fight, at which experts were called to explain what "chassis" and "bodies" really were, the magistrate observed, in dismissing the summons:—

"That he was quite satisfied with the expert evidence given by the defence. It was almost a certainty that neither the legislature nor the draughtsmen of the Act contemplated such a point as the one raised on the present summons, and for the simple reason that from the beginning of the motor car industry all manufacturers, traders, and dealers in cars regarded the chassis of a car as the motor car proper. The body formed no part of the car that had to be tested, viz., the machinery."

We trust this decision will have some effect in introducing common sense into the views taken by other magistrates on this question. The loosely worded passage in the statute has been continuously interpreted by police and magistrates in a manner in which the legislature certainly never intended, and in a way which has amounted to nothing more nor less than persecution of the manufacturer. The decisions of magistrates unfortunately do not count as precedents, but a Metropolitan Magistrate of Mr. Lane's standing commands so much general respect that we feel sure we shall hear less of these vexatious prosecutions in future.

Should be brought before the Royal Commission.

OF even more importance, however, is it that the matter should be forcibly brought before the Royal Commission, a point which we can rely upon the Society and the Joint Committee to do. Fortified with Mr. Lane's decision they will be able to make out a strong case that the phraseology for whatever section of the new Act may be devoted to this question shall be made clear and intelligible, and at the same time even indulgent. The obvious intention of Parliament was to afford a relief to manufacturers, and it is to be hoped that the Royal Commission will recommend that the new law shall be so drafted as to do so.

Commendable Enterprise.

ON more than one occasion have we made it our business to point out that for the British automobile industry to be placed in a position in which it can really satisfactorily compete with the great Continental manufacturers, what is needed is the establishment of works on such an extensive scale that advantage can be taken to the full of modern improvements in machine tools, organisation, and universal standardisation of parts. The Argyll Company have, as we chronicled at the time, recently adopted this line, and have laid down an immense works which, when completed, will enable them to turn out some 2,000 cars annually. But the Scottish enterprise, that same splendid combination of engineering and business capacity which has made the northern half of the United Kingdom—and particularly the neighbourhood of Glasgow—famous throughout the world, and which recently led to the winning of the Tourist Trophy in the Isle of Man by the Arrol-Johnston Company, has not stopped there. The organisers of the great Argyll undertaking have recognised that an outlet for their cars in the *centre of the world* is imperatively called for, and the same spirit which has prompted the great development of works in the north has now proceeded to the formation of an allied company which commands what we believe to be the largest showrooms in the Metropolis, whose business it will be to introduce the Argyll cars on an adequate scale to the London district. The combined enterprise and far-sightedness shown by both these great departures are a most encouraging sign for the future of the British industry. They also form a splendid recognition of the importance of the automobile movement, for when Scotch capital, controlled, as is universally recognised, by the hardest-headed people in the world, has shown itself willing to embark in automobile manufacture and distribution on such an extensive scale, even the most prejudiced opponents of the movement must recognise that its future is no longer in the slightest degree doubtful.

More Extortions by the "Familiars" of the (H)andover Inquisition.—There was a further bag of motorists and corresponding fines last Saturday at Andover, when, as usual, during the performance of a farce, facetiously called "Justice," sums varying from £1 to £10 were raked in for the relief of the local rates. The farce, also as usual, was under the direction of Colonel Harmar. With well simulated indignation, one of the police constables stated that a driver, when stopped in the usual trap, declared "It is no use talking to you, as you will only swear our lives away." In spite of this he was let off with the moderate fine of £3. Mr. George Burfit, of King Place, Baker Street, was fined £5, and Dr. William Freeman, Weyhill, and Mr. Albert Joseph Cox, of Wandsworth, were mulcted in £10 each, on the ground of it being their second offence, though if they often proceed through the Andover police trap they will very easily run up their fiftieth. "Here Satan's sole good work deserves insertion"—the Bench, either satiated with fines, or melting under the influences of the adjournment for lunch, let off a chauffeur with a fine of £1, as he requested them to "make it as light as they could, as his boss wouldn't pay his fines." No doubt his "boss" thought he deserved all he got, if he were foolish enough to drive anywhere near the (H)andover infected circle.

THE BRITISH ARMY AND MECHANICAL TRANSPORT.

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—General view of Hurley Camp, where the repair train was stationed during the recent military manoeuvres.

EVEN although Englishmen seem imbued with a love of criticising the organisation of our military forces, yet at heart there is no national institution so much beloved by the true Briton, nor one whose doings evoke so much popular interest, as the British Army. Certain departments are so unfortunate as to call forth adverse comment from an erudite and far-seeing Press, but for one section at least—the Mechanical Transport Corps—the *raconteurs* of the recent military manoeuvres have had unstinted praise. Of all military organisations, the most go-ahead is, perhaps, that which has to do with the mechanical transport of army stores. As in the case of other comparatively young institutions, its progress has been more easy because untrammelled by precedent, but however that may be, it is nevertheless certain that, under the guidance of Col. F. T. Clayton, C.B., this important branch of military transport has made exceptionally rapid strides ever since its inception. It was, in fact, due to Col. Clayton that this phase of automobilism came into existence at all, so it is to him that the British Army owes the introduction of traction-engines and other similar machines as a supplement to its existing system of horse transport.

There is nothing more necessary for the well-being of an army or the success of a campaign than adequate transport, and the army that does not possess it is certain, when engaged in active operations, to be sooner or later left at the mercy of its enemies. Animal transport will prob-

ably always survive to a certain extent for military services, but every year the importance and effectiveness of mechanical transport increases, and—appropriately enough—the military transport department of the British Army is one of the most efficient and progressive branches of the service.

A Lesson of the South African War.

At the present day, mechanical transport in the army may be said to have only just been born, but already it has done much good work. It was, as everyone knows, during the South African War that the new system received its real christening, and perhaps the most valuable feature of that trial was, as is usual with all first attempts, the lessons it taught as to the most suitable lines for future development. One of these morals was the absolute necessity for an efficient repair station capable of acting as a mobile base in time of war. Liability to breakdown is, of course, a factor of automobile traction which must ever be provided against, and, in the field it becomes, without adequate provision for contingencies, a menace to the efficiency of an otherwise well-organised system. Thus, in South Africa, it was the absence of such an element which constituted the greatest obstacle to the successful use of mechanical transport during the war, and it was owing to the presence of this formerly missing factor that Hurley Camp was able to lay claim to so much interest at the time of the recent manoeuvres.

Captain Hill. Major W. E. Donohue. Lieut. Blamey.

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—Officers in charge of the repair train at Hurley Camp. Major Donohue, who is Chief-Inspector of Mechanical Transport, is responsible for the technical equipment of the train.

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—Traction engines of 78th Company Army Service Corps at Hurley Camp, under the command of Capt. Hayter. These are the machines which actually carry out the transport work, and it is their presence in the Army which has called into being the repair train, which acts as a base for their operations.

The Repair Train.

Under the supervision of Major W. E. Donohue, Chief Inspector of Mechanical Transport, who has been assisted by Lieut. C. S. Lyon, there has now come into existence a unit of mechanical transport known as the "Repair Train," which is not only capable of forming an efficient base of a permanent character at which damaged transport machines may find speedy attention, but is also sufficiently mobile to readily respond to any call for its sudden translation which may be made at the instance of military tactics. In fact, mobility is the leading feature of the present train, which being the first of its kind, however, must not be considered as a final model. Other systems will be tried, and possibly something quite different may eventually be adopted, but no outcome of the future can deprive the present repair train of its very great interest, since it is the first successful attempt to provide the coping-stone for a definite system of organised mechanical transport.

The repair train, as we saw it at Hurley Camp—where the photographs illustrating this article were specially taken by us—consists of six wagons formed in two independent sections of three, each of which is under the control of its own steam traction engine. The engines are of a standard type, and the wagons themselves have been improvised from existing vehicles, so that their appearance must not be taken too literally as typical of a perfect example of a particular system. The first section is self-contained, the other section is more in the manner of a pantechicon for the removal of apparatus which requires independent floor space for its use. It is in the first section, for instance, that the machine tools are situated, while the second section affords a storage for the foundry and smithy plants, which obviously could not be erected as permanencies within the confines of a military wagon.

Electricity, the modern agent for mechanical power transmission, demonstrates here as elsewhere its peculiar adaptability to improvised surroundings, and in the first

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—First section of the repair train. The three wagons comprising this half of the train form travelling workshops and contain machine tools which are electrically driven. A dynamo is installed in the first wagon.

wagon of the train is installed a $6\frac{1}{2}$ kilowatt (8.7-h.p.) dynamo—which is at present belt-driven from the traction engine—for the supply of light and power throughout the camp. In the next wagon, is a 6-inch lathe and a milling machine, while the last wagon of this section contains a drilling machine and an “H.F.” vulcanising plant for the repair of the pneumatic tyres used on the motor cars now so largely employed by officers in the execution of their duties. Here then, in itself, is an efficient field workshop, but without the means of roughly fashioning articles from the raw material such up-to-date machinery would, of course, be practically useless. In the next section therefore, is contained all the apparatus necessary for the equipment of a foundry, a forge, and a carpenter’s shop. These departments have to be erected in the open, or with such shelter as can be improvised on the occasion, but they are naturally of a rough and ready character, and consequently do not

* *

RULES FOR MOTOR CARS.

THE following list of rules has been forwarded to Mr. S. F. Edge by the user of a Napier car. Mr. Edge has sent it to us for publication, as he thinks it contains many useful hints to anyone having a chauffeur and a motor car, as most of the points are applicable to any motor car :—

MOTOR CAR.

It is to be clearly and distinctly understood that each of the following rules is to be carried out faithfully, and that the evasion of any one of them will be looked upon as a serious offence :—

1. The chauffeur to commence his duties at 7 a.m., and the time from this hour until 8.30 a.m. to be reserved solely for the cleaning and general overhauling of the car.
2. At 8.30 a.m. the chauffeur must call for his orders for the morning.
3. The car and mechanism to be kept *scrupulously clean*.
4. Any negligence in the upkeep of the car which may tend to jeopardise the safety of the occupants when driving will be looked upon as an unpardonable offence, and will render the driver liable to *instant dismissal*.
5. It is to be clearly understood that when driving Lady ——— the car is not to exceed 15 miles an hour under any circumstances whatever, and in the streets of a town or other places where there is traffic, the speed should not exceed at most 7 or 8 miles an hour, and less according to circumstances.
6. Smoking is prohibited while cleaning or working on the car.
7. No so-called improvements or alterations are to be made to the working parts of the car without express authority.
8. Any complaint regarding the unsatisfactory working of the car through suspected structural defects is to be reported in writing. Arrangements will be made to have the car inspected at regular intervals.
9. The chauffeur is expected to be within call throughout the day, when the car is not being used by the family.
10. The car must never be put away at night without being cleaned.
11. Tools, spare parts, tyres and other accessories, when not in use, to be placed in the cupboards and shelves provided for the purpose.
12. When driving the car, every action should be gentle and not sudden, and corners should be taken slowly.
Use the brakes as little as possible.
Clutch to be kept well lubricated.
13. If the chauffeur considers that he has not time to look after the car conscientiously, he is to inform me in writing, when an enquiry will be made, and, if found necessary, the car will be left unused, at a time convenient, for a sufficient period for the chauffeur to complete his work.
14. A thorough examination should be made weekly by the chauffeur to see that the nuts and bolts are tight and securely fastened.
15. Care should be taken that every moving joint is lubricated directly before taking the car for a run. Such joints as radius-rod ends, spring clips, clutch actuating gear, &c., &c., also all grease cups, should be attended to.

greatly impede the general mobility of the unit as a whole.

Without going further into the details of its equipment, enough has been said to show that the train is a genuine attempt to meet the demands of a repairing base for a large mechanical transport corps. The present scheme provides, as we have already pointed out, a very mobile unit—for it can be on the road in two hours—and it is essentially a matter for the military authorities to decide how far this mobility should be sacrificed in the future on the score of economy. An alternative, for instance, would be to unpack everything in camp, which would render fewer wagons sufficient for the transport of the same machinery. Whatever may be the ultimate scheme, however, there is an underlying certainty of efficiency, for Major Donohue is most keenly alive to the technical requirements of any organisation of this nature.

(To be continued.)

* *

All accumulators must be kept fully charged with acid solution and current, and all electrical terminals kept clean and tight.

16. Petrol should only be poured into tanks when car is outside coach-house, as the close proximity of the gas-jet to car with full tanks would be a danger should this regulation be overlooked.

* * * *

Smoky Exhaust.—There is a witty and humorous writer on the *Westminster Gazette* who deals with motor car topics. Apropos of the present crusade of the police against the motor car with smoky exhaust, he quotes an article from *The Times* of 1838, which goes to show that in these respects, at any rate, the old steam cars—the promising but premature ancestors of the modern automobile which were driven off the roads by prejudice and prohibitive tolls—were, in this respect, unobjectionable. In the article in question occurs the following passage, apropos of Anderson’s steam carriage: “No noise is heard, no smoke, no unpleasant odour perceived, and the gallant, panting steed can gallop to his journey’s end untired and untiring. How admirable is this arrangement!” While we are informed that an even earlier steam vehicle on somewhat the same lines, for they had been running on the roads at this date some ten years, “made its way through a crowded passage without any perceptible impulse. There was neither smoke nor noise; there was no external force nor apparent directing arrangement; the carriage seemed to move of its own volition, passing horses without giving them the slightest alarm . . . going without the least vibration and preserving a balance in the most complicated movements.” Fortunately smoky and unpleasant exhaust is no more essential to the modern motor car than it was to its early predecessor.

THE President at the yearly gathering of the Royal College of Veterinary Surgeons, held on Monday last, was in an optimistic mood as to the future of the horse, and the probable failure of the motor car. Things are all very nice, he says, when a motor car is new, but when it gets old and defective then people go back to the horse. There are humours about the situation when a leading man in a profession which lives by the unreliability of the horse, looks forward with satisfaction to anticipated failures in the motor car. If the horse were absolutely reliable what would become of the Royal College of Veterinary Surgeons?

THE 18-H.P. REGENT CAR.—PART I.

A NEW car—which is known as the Regent—has just been placed on the market by Messrs. S. F. Edge, and the fact that this new model is being introduced to a critical motoring public by such a celebrated firm is in

carried in ball-and-socket joints by brackets at their forward ends. The propeller-shaft also is enclosed in a stationary tube which, being rigidly-attached to the axle casing, relieves the springs of any torque. Steering is effected by the usual type of worm-and-quadrant gear, but the tie-rod lies behind the axle instead of in front. Beneath the frame extends a metal sheath, which entirely protects the machinery from mud and dirt, while neat grease-cups are provided on all working joints that are not suitable for connection to the system of pressure-feed lubrication.

Transmission Gear.

Enclosed in the flywheel, is an ordinary type of leather-faced cone-clutch. The clutch-spring is very easily adjustable, and in order to enable the inner member of the clutch to be more easily dismantled when it is necessary to fix a new leather, the clutch shaft is made in two parts (Fig. 1), which are joined by a flange so that one of them (A) may be bodily removed in order to allow the other—

which carries the clutch—to be drawn back sufficiently for removal. The gear-box, shown separately in Fig. 2, is carried directly from the main-frame. The system of gears is the ordinary sliding spur-wheel type, and there is only one sliding member for introducing either of the three forward speeds and the reverse.

Both the through-shaft and the lay-shaft are mounted on substantial ball bearings, and the four keyways on the former, which carries the sliding member, are milled from the solid in accordance with the most up-to-date practice. A direct-through-drive is introduced on the top speed by means of a jaw-clutch, the two members of

The 18-h.p. Regent Car.—View of the new car which Messrs. S. F. Edge are now placing on the market as a low-priced up-to-date touring vehicle.

itself a guarantee of the high-class nature of its construction and workmanship.

The *raison d'être* of the Regent car in Messrs. S. F. Edge's showrooms is primarily its moderate price—as it is in order to meet the demands of clients who require a less costly car than the Napier, that this new model has been introduced. Up-to-date design, however, is the keynote of the Regent car, and both in general appearance and in mechanical detail the construction cannot fail to appeal to the fastidious. Strictly speaking, there is practically no innovation in any part of the mechanism, which has been constructed rather on well-tried lines than with a view to exploiting any novel features. In detail, however, there is distinct evidence of careful consideration as to accessibility and efficient lubrication, while purchasers of these cars reap the benefit of Mr. S. F. Edge's personal experience with the Napier vehicles, which have so many refinements conducive to considerate driving and the comfort of passengers.

Leading Features.

This car is of the live-axle type; it is fitted with a three-speed gear-box giving a direct drive on the top gear, and the four-cylinder engine is normally rated at 18-h.p. With the exception of the engine, ball bearings are fitted throughout, including the front wheels. The rear wheels are mounted directly on the live axle, which is itself carried on ball bearings. The frame is of pressed steel, narrowed in front of the dash to secure a wide steering lock, and is carried on semi-elliptic springs both in front and behind. The rear springs lie outside the frame, and they are shackled at both ends, the drive being transmitted through long radius-rods which are hinged to the axle casing, and are

Fig. 1.—The 18-h.p. Regent Car. View showing the construction of the clutch-shaft which is made in two parts, so that when the short, flanged portion, A, has been removed, the inner member of the clutch can be easily dismantled. The pipes for the pressure feed-system, the strainer, B, for the petrol, and the interconnection, C, between the side-brake and the clutch are visible in this illustration.

which are formed on the pinion attached to the driving shaft, and on the sliding member, respectively. The propeller-shaft, which is, as has already been mentioned, enclosed in a stationary casing, is universally jointed to the gear-shaft, and at its rearward end it is supported by a large ball-bearing in the back-axle casing. The back-axle, which is shown in Fig. 3 is of substantial construction, and is well stayed, while an important feature of its design—which deserves to be more generally adopted—is the four-part construction of the casing, with the formation of a horizontal joint between the two central members. This feature is a real convenience, for it enables a thorough examination of the driving bevels to be made with a minimum amount of trouble, and without the annoying necessity of dismantling the entire back-axle—imperative with the two-part construction more generally used. As for the gear-box, so for the back-axle-casing, a hinged inspection cover of useful dimensions is provided above the gear-wheels. The rear-wheels are keyed directly to the ends of the live-axle, which is supported to the axle-casing by ball-bearings.

Brakes.

The usual system of brakes is provided, a side-lever operating the brakes on the rear hubs, and a pedal actuating a brake on the driving-shaft. All the brakes have metal-to-metal surfaces, and those on the rear hubs are of the internal expanding variety. The foot-brake is situated immediately behind the gear-box, and is visible in Fig. 2. It is of the ordinary shoe type, and is operated through a toggle-lever. The hand-brake is inter-connected with the clutch, through a rod, C, visible in Fig. 1.

(To be continued.)

Fig. 2.—The 18-h.p. Regent Car.—View of the gear-box, showing the milled key-ways for the sliding member. Three speeds and a reverse are available, the top gear giving a direct-through-drive.

Fig. 3.—The 18-h.p. Regent Car.—View of the back-axle, showing the four-part construction of the axle-casing which enables the upper central portion to be removed for the purposes of inspection.

THE enthusiast or maniac who, after placing himself flat in the road in front of Dr. Stanley Tressider's car some little time ago, commenced slashing at the tyres with a knife, and when the doctor got out to object attacked him also, has just been sentenced to eight months' hard labour.

So much fuss has been made about petrol and

petroleum running into and polluting the ponds on country roads from motor cars, that it is amusing to learn that the best and most effective method of getting rid of mosquitos is to pour a certain amount of petroleum on the surface of all stagnant ponds. It is on the surface of such ponds that the mosquito develops in the larva stage, and the mosquito larva does not take kindly to petroleum as a form of nourishment.

A 1906 MERCEDES CAR.—THE NEW 70-H.P. MODEL.—PART II.

(Concluded from page 1203.)

Fig. 5.—View from the "off" side of the new 70-h.p. Mercedes Chassis.

The Chassis.

OUR four views—Figs. 1, 5, 6, and 7—of the chassis effectively show the general arrangement of every part, and therefore render it unnecessary for us to enter into any lengthy description concerning it. Comparatively little change of a sweeping character has, moreover, been made in this new model. In Figs. 6 and 7, however, the compact form of the new gear-box can be noticed, while in both those illustrations, and also in Fig. 5, the long dust-excluding casing that extends back from the engine beneath the entire transmission-mechanism is visible. Attention might be drawn, too, to the fact that the filler-cap for the petrol tank is now brought out at the back of the vehicle. The main-clutch, which is still of the "scroll" type, has

undergone a slight modification, for the oil-retaining casing, immediately behind it, now fits closely round the clutch-shaft. On former models, there was quite a considerable space between the shaft and this casing. A flexible pipe serves to lubricate the sliding sleeve with which the clutch-fork engages, and, as before, there is an intermediate ball-bearing for supporting the long propeller-shaft, midway between the clutch and the gear-box. Either of the three pedals—the two brake-pedals or the clutch pedal—is capable of disengaging the clutch.

Fixed lengthwise beneath the frame, on the "near" side, is the exhaust-box, and outside the frame, near the dashboard, are the lubricating oil tank and the tank that contains cooling water for the brakes.

Fig. 6.—The 70-h.p. Mercedes Chassis—1906 model—as seen from above. The very compact gear-box, which gives a "direct drive" on the top gear, is well shown in this view.

Fig. 8.—The 70-h.p. Mercedes engine, fixed in place in the 1906 Chassis. View from the "off" side, showing the new carburettor, the modified igniters, and part of the magneto and the governor.

The Brakes.

Following the customary Mercedes practice, two independent foot-brakes are provided, both of which are fitted close up to the gear-box. One is in the same position as on most chain-driven cars—on the differential countershaft—and the other is fitted to the projecting front end of the lay shaft. Both brake-drums can be kept cool when in use by a stream of water that can then be directed inside them, the water being fed, when desired, from the pressure-tank above referred to.

The novel feature of these brakes on the 1906 model is that they can be adjusted by hand, without the use of any kind of tool. One brake-band has—as seen in Fig. 7—a wing-nut, E, for this purpose, and the other has a small hand-wheel, E', instead. Both the wing-nut and the hand-wheel are rendered self-locking.

Concerning the hand-operated hub-brakes on this vehicle, little need be said. They are of the internal expanding type, and are rendered compensating by a steel cable in the ordinary way. On this latest model, no sprag device is employed, the ingenious mechanism that was adopted on the earlier 70-h.p. cars having evidently proved itself to be unnecessary.

The Engine.

In Figs. 8 and 9, the shape of the castings that form each pair of cylinders is well shown, as also are the yokes that hold down the inspection plugs above the valves. The exhaust-valves are on the "near" side (Fig. 9),

the inlet-valves and the igniters are on the other side (Fig. 8), and the main castings are given a distinctive tapering shape around the valve-chambers.

In Fig. 8, the new carburettor, of which we have already given a full description, will be easily recognised, fixed in position by its branched induction-pipe. The throttle-valve is controlled from behind by rods, that connect it with the governor and with the "accelerator" pedal and hand-lever. In just the same way that one port in each cylinder-casting feeds each pair of inlet-valves, so a single port, on the opposite side, serves for each pair of exhaust-valves—and the unusually simple exhaust-pipe-fitting is only held in place by four studs.

A slight change has been made in the design of the igniters, these now being somewhat more compact than formerly. They occupy, however, the same positions as before, and have

small cocks fitted in the main castings—immediately above the contact points—to enable them to be cleaned with petrol, and to facilitate starting, when necessary; the cocks are similar to those fixed centrally above the pistons—for introducing paraffin to clean the piston rings.

The lower portion of the crank-chamber, which is formed by two aluminium casings, is secured direct to the side-members of the frame, and between it and the upper portion are held the three ball-bearings that support the crank-shaft. At the front end of the crank-chamber, the gear-wheels which drive the two cam-shafts are completely enclosed in an oil-tight casing, and this casing is of sufficient size to also contain the two additional spur-wheels which operate the centrifugal pump,

Fig. 9.—View, from the "near" side, of the 70-h.p. engine on the 1906 Mercedes Chassis.

Fig. 7.—The central portion of the new 70-h.p. Mercedes Chassis, as seen from the rear. In this illustration the easily detachable inspection-cover has been removed from the gear-box, and the spring clips which normally hold it down in place are clearly visible.

on the left side, and the magneto, as well as the governor, on the right side; these auxiliary parts are separately bolted down to the crank-chamber, and are driven through flexible jaw-couplings that enable them to be easily removed when desired. Fitted in conjunction with the exhaust-cam-shaft, is a half-compression device that can be brought into play by a handle in front of the radiator; it causes the exhaust-valves to be lifted during the first part of the compression strokes. The governor, which is of the centrifugal type, lies between the magneto and the spur-wheel which drives them; it is not enclosed in any way, and its sliding sleeve is connected up in a simple manner with the throttle-valve. As usual, the igniters are actuated from the same cam-shaft as the inlet-valves, and the rock-shaft by which they are simultaneously "timed" lies along, outside, the crank-chamber.

Apart from "timing" the ignition—which is effected by the smaller hand-lever above the steering-wheel—the entire control of the engine is by the throttle-valve. The governor normally tends to close it automatically as the speed increases, but it can be opened to the desired extent by the hand or the foot of the driver. The accelerator pedal lies in a convenient position for the left foot (as seen in Fig. 7), and the corresponding hand-lever is above the steering-wheel. There is no connection whatever between the clutch-pedal and the throttle-valve.

In Fig. 7, a very good idea can be obtained of the size of the fan fly-wheel; in Fig. 8 the position of the pressure-valve is well demonstrated; and in Fig. 9 it will be seen that the necessary connection between the pressure-valve and the exhaust is made by a pipe leading into the rear cylinder-casting close up beneath the rearmost exhaust-valve.

Lubrication and Dashboard Fittings.

Not only is the large 12-feed lubricator—in the centre of the dashboard—fed by pressure from the supply tank at the side of the car, but a feed pipe is now led from that tank to the hand-operated lubricator, Q, also. In this way, it is no longer necessary to fill the glass container by hand, for the oil flows into it directly the cock is opened. The lubricator, Q, is of that type in which a hand-pump is fitted for forcing oil into the crank-chamber. From the large multiple-feed lubricator, the supply to which is controlled by a central cock, the pipes are led to every bearing on the engine, and also to the steering-gear.

To the left of the large lubricator (Fig. 7), is the cock, Q², which has to be opened when water is required in the brake-drums, and to the left of this again are the greaser, Q³, and the pressure gauge-cock, Q¹. The water to the brake-drum is also controlled by a valve that opens when either of the brake-pedals is fully depressed, and the driver is enabled to see when it is flowing through the gauge-glass, near the cock, Q². The greaser, Q³, is connected solely with the circulating pump, and ensures proper lubrication of the important bearing on its shaft. The cock, Q¹, is provided in order that the pressure-gauge may normally be allowed to remain at rest, and thus the life of the gauge be materially prolonged; the gauge is only needed to indicate the pressure in the "feeding" system occasionally—when pumping up initially by hand, or when there is any doubt as to the proper working of the automatic valve—and no useful purpose is, therefore, served by leaving it "on" continuously.

The only remaining fitting on the dashboard to which attention need be drawn has already been mentioned, this being the small hand-lever, H¹. It constitutes a part of the new Mercedes carburettor, and allows the driver to instantly and entirely cut off the petrol feed. As previously explained, it prevents any more petrol from entering the float-feed-chamber—and would therefore prevent waste if the carburettor were inclined to flood when the engine were at rest—and it also cuts off the flow of fuel to all four jets.

Table of Reference Letters for the 70-h.p., 1906, Mercedes Car.

Change-Speed-Gear.		Starting-Handle.	
A	Direct-drive bevel-pinion.	G	Catch for starting-handle.
A ¹	Bearing-bridge for A.	Carburettor.

		Fittings on Dashboard.	
		Q	Hand-operated lubricator.
		Q ¹	Cock for air-pressure gauge.
		Q ²	Cock for brake-cooling water.
		Q ³	Greaser for circulating pump.

THE EMPIRE SPRING WHEEL.—PART I.

OF all the wheels which have hitherto come before our eyes, called the "Empire," which has been brought to the attention of the public by A. S. F. Robinson—the inventor of the well known governor which bears his name—is perhaps the most original, for it shows in its design the careful evolution of a principle which has apparently not previously been attempted in the construction of resilient wheels. If for no other reason than that laminated leaf-springs (instead of those of other patterns) are employed for the purpose of giving resiliency, the "Empire" wheel would be deserving of special attention from those to whom a satisfactory spring wheel is becoming a matter of some moment.

Even those motorists whose interest in matters technical is of the most superficial nature will have at least noticed that leaf-springs are almost exclusively used in all cases where the resilient member, whatever it may be, is subject to shocks of greatly varying intensity. Where helical springs are employed under such conditions, it is usually because of their greater convenience and their extreme compactness. It is, in fact, doubtless due to their compactness that helical springs have been adopted so largely in the design of spring wheels.

It is not so much for the mere employment of leaf-springs, however, that Mr. Robinson deserves credit for his invention, as for the "compensating system" which forms its essential feature. The idea of compensating a system of springs is nothing new in itself—it has been employed in certain types of locomotive construction for years—but, in order to derive its benefits and also to obtain the reliability that accrues from the use of leaf-springs, in such a comparatively diminutive member as a wheel, very careful thought and construction are naturally necessary.

Principle of the Wheel.

The term "compensation," when applied to a system of springs, means that the individual springs are so connected between themselves that one and all are compelled to take whatever load may be imposed on either one of them. Usually the end of one is more or less directly coupled up to the end of the next, instead of being separately and directly fixed to some independent body, and the result is that the deflection of one essentially involves a deflection of the next. In this way the load is not equally *divided* between the springs in such a way that the load on each is reduced, but every spring is called upon to carry the full load. The further point, however, which has to be recollected when considering any such system of springs as this, is that, until the load imposed direct upon any spring is greater than that

already imposed on any other, none of the springs in the whole system undergo any increase of strain whatever; this means, in short, that every spring in the whole system is deflected to an extent that depends solely upon the strain on the spring which is carrying the greatest load, and that supplementary loads of smaller magnitude imposed on any other springs have no effect at all on their deflection.

With a view of showing the advantages of compensating the springs in a spring wheel, it is necessary to remember the manner in which the load on a wheel is transferred from place to place over the rim of a wheel as the vehicle moves along. This point is best illustrated by imagining the rim to be cut away altogether, so as to leave the spokes directly in contact with the ground. Under such conditions, the load would be supported either by one or by two spokes at any given instant. Now, if each spoke has a spring in it, it will be obvious that each spring will at one instant be carrying the full load, at another instant half the load, and the next instant no load at all.

If the rim be now replaced, the immediate effect will be to distribute the load simultaneously upon all those spokes which, at any moment, point radially downwards; this load is not divided equally, for that spoke which is vertical still receives the largest share, but still it is divided, and instead of the jerky action described

Fig. 1.—The "Empire" Wheel. View of a Peugeot Car fitted with an experimental set of spring wheels.

above the maximum stress on each spring is not only reduced in magnitude but the period of its application is considerably increased. Many spring-wheels are constructed on this principle; the springs may not be actually inside the spokes, but they are arranged radially from the hub, and the consequence is that the maximum amount by which each and every spring will, in turn, be stressed depends on how many springs can be used in each wheel. In itself the maximum load on a spring is unimportant, for springs can be made to stand any ordinary load likely to be imposed in motor car practice, but as determining the amplitude of the "cycle" or variation of stress which occurs in each spring it is very important. It will be obvious that, in the arrangement of springs under consideration, those pointing upwards at any instant cannot be loaded at all, so that every spring of the entire system must, therefore, undergo a "cycle" of stresses, and it merely depends on the number of springs whether this cycle will impose a severe strain on each spring or not.

It is principally as a factor producing molecular fatigue that the magnitude of this varying strain is important, but there is also the loss of engine-power which it occasions, for the release of one spring cannot entirely

compensate for the work done in compressing the next. What is wanted, therefore, is some means of reducing the amplitude of the "cycle" at the other end, in fact, some device whereby the springs are prevented from going back to their unloaded state at all. There are two ways of doing this with leaf-springs, one is to initially stress each of them individually until they can support the normal load without bending, and the other is to "compensate" them as Mr. Robinson has done in his wheel—so that each spring is always loaded as much as any other in the system. The first of these methods produces what is virtually a "solid" wheel within the limits of normal loading, although the wheel is still capable of absorbing sudden shocks; but, with the second method, the wheel is a spring wheel always.

Although by compensating the springs, the amplitude of the cycle is reduced, it is impossible to eliminate it altogether because, no matter how many spokes there may be in a wheel, there must always be a series of intermediate periods when the number of spokes which

(To be continued.)

THE LEMPEREUR NON-SKID.

BOTH at the official trials in France, and at those held by the A.C.G.B.I. in this country, the device invented by M. Lempereur—for which Messrs. Mann and Overton are sole concessionaires—secured the gold medal. Recently, how-

sisting of an adjustable hook which can be screwed up until the band is drawn tightly down on the tread of the tyre. It is thus no longer necessary to deflate the tyre in order to attach the non-skid. Another modification is the provision of two leather strips under the chains, which protect the tyre from direct contact with the metal, and also enable the transverse plates to obtain a better grip on the ground.

AMONG the many contributions to the dust problem we direct the attention of our readers to a paper on the subject in a recent number of *Nature* (for September 14th), by Mr. W. R. Cooper. The article in question contains a *résumé* of what has been already done in regard to experiments in the effect of different shapes of car bodies in raising dust, and adds a number of experiments of the author's own which were conducted with a simple apparatus, consisting of a single cycle wheel dragged by a special means over dusty surfaces so as to reduce the problem to its simplest dimensions, and enable the effect of various surfaces in the neighbourhood of the wheel to be studied. The article is copiously illustrated, and shows the relatively small amount of dust produced by a thoroughly hard pumped-up tyre, the greater amount of dust produced by a slack tyre, and the varying amounts of dust produced by different forms of surface, and different planes arranged in the neighbourhood of the wheel. The article, of course, does not claim to in any way have solved the problem, but is a useful contribution on what may be termed the elements of the subject.

THE LEMPEREUR NON-SKID.—Views showing the modified form of this device, which is no longer made as an endless band, and is now fitted with leather strips to prevent the metal touching the rubber of the tyre. The special fastener, A, by which the non-skid is secured in position, is also shown on enlarged scale in this illustration.

ever, this non-skid has been somewhat modified. Formerly there was an endless band of loose metal plates attached to two chains, which relied on the inflation of the tyre for fixing it in place. Now, however, the chains are provided with a pair of special fasteners, A, each con-

THE clipped dog is one of the products of civilisation on the aesthetic value of which opinions may differ. The clipping is probably satisfactory to the dog in summer, and almost equally certainly gives him rheumatism in winter, but as the craze has been established, the petrol engine has adapted itself to the circumstances, and one of the amusing inventions, which is becoming a recognised institution in France, is a movable clipping arrangement for poodles in which the activity of the men who usually turn the handle of the clipping apparatus is replaced by a petrol engine mounted on a truck.

REPAIRING A PUNCTURE—A MODERN METHOD.

(Concluded.)

THE patch is now ready for vulcanisation, but before putting it on the vulcaniser care must be taken to see that the pressure gauge is exactly at 65 lbs. per square inch. When the pressure has been obtained by adjusting the telescopic slide on the burner, a piece of paper dusted with French chalk should be placed over the repair, and the patch laid face downwards on the vulcaniser. The press is then put in position, and screwed down *thumb tight*, after which the tyre is allowed to cook for just fifteen minutes, the steam pressure being maintained

been sufficient to indicate the principle of the process. In the case of a puncture, it would, of course, suffice to poke the end of a narrow strip of compound into the hole and form a tiny patch on the outside to fill a very small depression, which should be cut in the tyre in the same way that the edges of the larger burst are bevelled.

With a very large gash, on the other hand, it is uneconomical to use compound throughout, because a piece of old inner tube roughly cut to shape may be inserted, after bevelling the edges, and vulcanised in

Fig. 9.—Afterwards apply a coating of cement.

constant throughout. After the patch is vulcanised, the tyre should be quickly removed, and dipped in cold water; this is not an absolute necessity, but it is a precautionary measure, for the cold water shrinks the rubber quickly, and closes up any minute gas bubbles which might possibly have been formed during the process of vulcanisation.

Fig. 11.—Wait until the cement has become "tacky" before the first strip of compound is applied as here shown. Remember to warm the compound before using in order to make it thoroughly plastic.

place as if it actually formed part of the original tyre. When a patch of this description is longer than the vulcaniser will accommodate, the cooking may be per

Fig. 10.—Don't forget that a piece of paper must be inserted to protect the opposite wall of the tyre.

The repair is now complete, and instead of the rough plastic yellow compound there appears a perfectly smooth elastic insertion of grey rubber which, if the operation has been properly carried out, is indistinguishable in substance from the original material of which it now forms part. Not only is there this similarity in substance, but there is no necessity for the new material to be any thicker than the old, and the fact that a sufficiently strong repair can be made by a flush joint is a feature which those who have experienced the trouble arising from the heat generated by a patch on a tube will readily appreciate.

The foregoing description is an indication of how a vulcanised repair can be accomplished by an amateur. Although only one case has been illustrated, it will have

Fig. 12.—Work the strip of compound gradually towards the centre until the hole is entirely filled in, then "caulk" all protruding edges with a penknife. The repair is then ready for vulcanisation.

formed in sections, care being taken to see that the extreme edge of each "bake" is properly vulcanised by allowing this portion to come in contact with the vulcaniser when the next section is being "cooked."

Steam is used in the process of vulcanisation, because it offers a comparatively easy means of obtaining the required temperature and of maintaining it constant. The temperature—which in this case is indicated for convenience by a pressure gauge instead of a thermometer—is higher than it is in the usual process of tyre manufacture, in order to prevent the other part of the tyre from becoming affected by any prolonged "cooking." The compound has, for this reason, to be specially prepared in order to render this rapid vulcanisation possible and effective.

THE ARGYLL INVASION OF LONDON.

The Argyll Company's special train, which arrived last week in London carrying a huge consignment of Argyll Cars, direct from Glasgow. This train was made up of no less than 30 trucks, all carrying new cars for the London depot. This is the largest consignment of motor cars of the same type which has ever been delivered in one lot.

RANGED round a banqueting table set in the form of a horseshoe, about fifty friends and representatives of the leading general and technical Press last Tuesday night foregathered at the Trocadero Restaurant to wish luck and to welcome a bold and important venture which has been established in London under the title of Argylls London Limited, for the purpose of handling in a very extensive and exceptional form, the cars which are now so well known under the title of "Argyll," and built in Glasgow by the Argyll Motors, Limited. There was no mistake as to the genuine welcome which was accorded to those responsible for this very important scheme, as it was felt that, irrespective of the gain which it was confidently anticipated would accrue to the immediate promoters of the undertaking, the mere fact of opening up so extensive a showroom as that which the new company possess in Newman Street, Oxford Street, and the facilities which are to be afforded to the general public to select a car—and if necessary drive straight away with the selected machine—must necessarily further open the eyes of all as to the growing importance of the industry, and show how utterly futile it would be for the rabid and prejudiced anti-automobilists to endeavour to stem the tide of prosperity which the enterprise and initiative of British manufacturers is now causing to flow with so strong a stream.

Immediately concerned in the new company is Mr. Eustace H. Watson, who, as chairman of Argylls London Limited, occupied the chair on Tuesday evening, whilst he was supported by Mr. Alec Govan, to whose indefatigable energy the success of the Glasgow Company is due, and by Mr. W. Alex. Smith, who has financially supported Mr. Govan's commercial instincts so generously, with the result that one of the largest automobile factories in the world has been constructed, where all-British cars of various powers are being manufactured to the benefit of Great Britain, in numbers which have hitherto never been equalled in this country, certainly not exceeded.

During the evening, some interesting particulars were supplied by the chairman, Mr. Watson, in respect to the enormous undertaking which has grown up round the manufacture of Argyll cars. At the new works alone, which are about two miles below Loch Lomond, 80,000 tons of material had up to the present (since April) been employed for construction, whilst at least 150,000 tons

would be ultimately required for their completion. The ground which the company owned, and which would admit of expansion to almost any extent, was fully sixty acres, whilst the present buildings covered the huge area of twelve acres. Of this, the machine shop alone occupied $2\frac{1}{4}$ acres, and although the works were in no way as yet capable of employing their full complement of men, about 2,000 employees were at present engaged in the construction of the company's vehicles. When the works were in full operation, the output would be at least 2,000 cars per annum. Dealing with the new London premises, the total floor space is 27,000 square feet at present, whilst extensions have already been arranged for, giving an additional 17,000 square feet.

Accommodation is at present available for 40 cars—subsequently for 60 cars—at the same time. The main principles which will govern the company's business will provide for the actual selection by purchasers from stock, so that they may try any car that is on view at a moment's notice, and may there and then take it away with them, when completely satisfied. By way of a commencement, a special train was run from Glasgow to London last week with a portion of the first delivery of these cars, this train consisting of no less than 30 trucks, a photograph of which we are able to reproduce above. Repairs of every character can also be dealt with promptly on the premises, a workshop having been fitted with the very best machine tool equipment, whilst a selected and qualified staff of mechanics has been brought from the Glasgow works to ensure perfect workmanship. One of the most important features of the London depot will be the stocking of a complete set of spare parts for every type of Argyll car, and the system will provide for the immediate despatch to any address of any part required. An equally important step is being taken in regard to a stand against the scandal which exists in many directions of giving "tips" to drivers of cars. Under no circumstances will any such donations be permitted, and the most drastic steps will be taken in the event of even the smallest suggestion being made in this respect. By way of compensating the driver, however, for the absence of such illicit commission, the company are instituting a prize competition by which the driver of every Argyll car will receive, for running and driving his car economically for

a distance of 5,000 miles, a cash prize of £5 in addition to a certificate setting forth the recipient's qualifications as a careful and economical servant. For this purpose, maximum sums are specified by the company which should not be exceeded for the maintenance of the cars of various sizes, the prize and certificates being based upon these figures.

In the course of the evening Mr. W. Alex. Smith, the chairman of the Glasgow company, paid a very high tribute to the ability and industry of his colleague, Mr. Govan, saying that the remarkable success of the Argyll firm was almost entirely due to him. Referring to Mr. Watson, the managing director of the new London concern, Mr. Smith also expressed the great satisfaction which he and the Glasgow concern felt at having so excellent a business man to look after their interests in the Metropolis, and with the fine premises that had been secured at Newman Street.

The toast of the "Automobile Movement" was dealt with by Mr. Rees Jeffreys in a very able speech, who, as usual, was carried away by the earnestness with which he deals with any subject with which he is closely allied. He naturally dilated upon the importance of the Motor Car Commission and its influence upon the future of the industry, and he ridiculed the fancy picture of the £1,000 car and its owner with unlimited wealth. The

real state of affairs was gradually being understood, and from the marvellous mass of statistics which were now being collected for the assistance of the Royal Commission on the Motor Cars Acts, it was becoming clear that the majority of cars were in the hands of men who were anything but wealthy. They were largely in the hands of medical and other professional men, who found them of inestimable value in daily rounds, and cheaper, moreover, than the older method of horse and trap. He felt convinced that, with the unexpected response which had been made by every class of the community in regard to the use and enormous advantages of motor cars, the evidence which the Club, the Motor Union, and other bodies would be able to place before the Royal Commission, would enable the case for the automobilist to be placed in such a strong and reasonable light, that he had the greatest hopes of a generous report which would naturally follow the production of the facts which were now being put into presentable form. In regard to increased taxes on automobiles which have been suggested, it should rather, he thought, be the reverse, in view of the saving which followed to ratepayers in many directions by the adoption of motor vehicles for municipal purposes. He would even go as far as to suggest that ratepayers ought to offer a bonus to motor vehicle manufacturers.

RACES, RECORDS, AND TRIALS.

HENRY EDMUNDS HILL-CLIMBING TROPHY.—Mr. F. Potts' winning 30-h.p. Daimler Car, driven by C. Grinham, at the start.

Henry Edmunds Hill-climbing Trophy.—Last week for the second time this trophy was contended for, and in this instance secured by a 30-h.p. Daimler, owned by Mr. F. A. Potts and driven by Mr. C. Grinham. As previously announced, Mr. Campbell Muir, who won the trophy in the first instance at Castlewellan, in Ireland, in 1903, did not enter to defend his title to the Cup, and the entry list, originally very meagre, amounting only to seven competitors, was reduced at the starting line to four only. This was unfortunate, as the hill

at Blackdown Park, Fernhurst, Sussex, which was courteously placed at the disposal of the Automobile Club by Mr. F. S. Philipson Stow, is an exceptionally good one for testing touring cars on a severe grade. Possibly the scarcity of entries and interest in the contest may be accounted for from the fact that no times are published by the club, and consequently little or no general interest can possibly accrue under the circumstances. The competitors who actually took part besides the winning Daimler, were Mr. F. R. S. Bircham's

Minerva ; 7, Mr. T. B. Browne, James and Browne ; 8, Mr. C. Harman Wigan, Vinot et Deguingand ; 9, Mr. D. Citroen, Minerva ; 10, Captain W. H. Bennett Dixi ; 11, Mr. Cyril C. Maudslay, Maudslay ; 12, Mr. John S. Napier, Arrol-Johnston ; 13, Mr. R. Dennis, Dennis ; 14, Mr. R. Dennis, Dennis ; 15, Mr. Harry Smith.

Maidenhead Dust Trials.—On page 1199 of our issue of September 30th dealing with this event, we erroneously described the car in the illustration in the centre of the page as representing "An Argyll Car coming up the Course." In reality, however, the car was a Clement belonging to Mr. J. F. Hawkins, the County Surveyor of Berkshire, who personally drove the car during the trials, and is taking very great interest in the experiments.

Brighton to Edinburgh Without Changing Gear.—Among the advantages of the 6-cylinder Napier car, a feature which renders it particularly attractive to those who know it, is that it can go practically anywhere on one speed—the top speed—without change of gear.

To demonstrate this Mr. Edge is arranging to make a test run from Brighton to Edinburgh on the 11th or 12th inst., in which he will prove that a 6-cylinder car can be driven the whole way on the top gear without any change. It is not to be imagined that the car will be

HENRY EDMUNDS HILL-CLIMBING TROPHY.—Mr. Huntley Walker's Darracq Car, which when near the summit at this Fernhurst climb, burst a tyre when going "all out" and crashed into a tree. The occupants fortunately escaped. As usual, the car has been widely reported as "completely smashed," a description which is somewhat belied by our photograph.

24-36-h.p. Itala ; Mr. S. N. Bankhart's 24-h.p. Rochet-Schneider, driven by Mr. Morgan Donne ; and Mr. A. Huntley Walker's 70-h.p. Darracq, driven by himself. Although the roads in the country were very heavy, the surface of the test hill was in good condition, and enabled Mr. Potts' Daimler to get up in good time, something under 2 minutes. The Itala car was next best in form, but unfortunately the Rochet-Schneider had pressure-feed trouble, and ultimately returned to the starting line for a second try. Mr. Huntley Walker's Darracq, when taking the acute corner towards the summit, burst a tyre, and after running over the grass, collided with a tree, damaging the car somewhat severely. Fortunately no harm came to either the driver or the passengers, although the latter left the tonneau somewhat hurriedly and without any effort on their own part, the mechanic having with remarkable agility jumped from the car when he saw the accident was inevitable. Mr. Huntley Walker, although shaken, does not appear to be any the worse for the mishap.

Tourist Trophy Race, 1906.—As a practical demonstration of the importance of this race and of the principles involved, already 15 entries have been received for next year's event. The regulations, in the meantime, will be carefully revised, and the lessons taught by the recent race as far as possible embodied. The entries so far announced are as follows: 1, Mr. John S. Napier (holder of trophy), Arrol-Johnston ; 2, Mr. A. Rawlinson, Darracq ; 3, Mr. A. Rawlinson, Darracq ; 4, Hon. C. S. Rolls, Rolls-Royce ; 5, Hon. C. S. Rolls, Rolls-Royce ; 6, Hon. C. S. Rolls,

VANDERBILT CUP RACE.—The 40-h.p. White Steam Racer, which was driven by Mr. Walter C. White in the American Eliminating Trials. Mr. Walter White is at the steering wheel. This special road racer, which has a very long wheel-base, has the main-frame hung beneath the axles, and the entire build is unusually low. Behind the driver's seat the supply tanks are fixed well above the axle, and in front is the "engine-room" forming the aft portion of the huge bonnet; the forward part of the bonnet has vertical finned tubes around the sides and front to constitute the condenser. All the control levers and pedals are on the left side—where the driver sits—but an emergency hand-brake is fitted outside, on the right, to be operated by the mechanician.

VANDERBILT CUP RACE.—The American Eliminating Trials. Bert Dingley on Mr. A. L. Pope's 60-h.p. Pope-Toledo, finishing in the race. Dingley was the first to complete the full course, his time being 2 hrs. 50 secs. for the 113½ miles.

provided with specially low gear for the occasion. On the contrary, it will maintain a good average touring speed within the legal limit throughout the run, and timekeepers will observe and note from start to finish of the run what the average speed actually attained is.

The route from Brighton to Edinburgh will be through Handcross, Croydon, London, Hatfield, Stevenage, Biggleswade, Stamford, Newark, and Doncaster, where the car will stop on Wednesday night, and then straight through Darlington, Durham, Newcastle, and Berwick to Edinburgh. The car, which will be driven by Mr. Cecil Edge, will start every morning at 6 o'clock and run to a time schedule of a little under 20 miles per hour, and immediately prior to the long journey it will be run at its best speed at Brighton, after which it will be driven straight away without any alteration whatsoever.

THE drivers of Herr Jellineck's three Mercedes in the race on October 14th on behalf of Germany, will be Messrs. Foxhall Keene, Jenatzy, and Warden. Jenatzy starts No. 1 in the race.

THE multiplicity of contests throughout America has resulted in a suggestion that there should be an arrangement whereby competitions generally should be abandoned, and that a series of twelve "America" trophies should be established by the chief governing bodies, to be divided equally between speed, touring, and commercial vehicles, the classification in each of these classes being determined by cylinder capacity, combined with weight of vehicle, and, in the case of commercial vehicles, the load carried. The American Automobile Association are named as the managers of this series of contests.

VANDERBILT CUP RACE.—Mr. H. S. Houpt's 60-h.p. Thomas Car, which was driven by M. Roberts in the American Eliminating Trials, and made the fourth best time of 2h. 29m. 40s.

Chateau Thierry Hill-Climb.—For the fourth year in succession this famous hill-climb was successfully carried out on Sunday last under the auspices, as usual, of *L'Auto*. Some alteration in the severe bends on the hill had this year been made, so as to enable the racing cars to participate in the event with safety, as well as in the Gaillon Climb on October 15th. Last year, owing to the high speeds which had been attained by racing cars, it was not deemed prudent to let any of the monsters take part in the race, they being confined to the Gaillon Hill-Climb, whilst tourist vehicles only ascended Chateau Thierry. Even after the alterations this year, it was deemed necessary at the last minute, owing to the state of the road, to time the racing cars over the standing kilometre only, thereby avoiding the dangerous turn which would otherwise have had to be taken at high speed, if the standing mile had been timed as originally proposed.

The only cars which were timed over the mile were the small fry in the Tourist class, ranging from 8,000 francs downwards, and the heavy vehicle section. Two new classes were introduced this year, viz., the class just mentioned for wagons and omnibuses, and another for tricars. In the former the best time was made by the Automoto wagon, of 9 min. 3 $\frac{2}{3}$ secs., whilst in the latter, M. Riviere, who took part in the recent Auto-Cycle Club's Reliability Trial in England, again driving a Mototri Contal, made the remarkably fine time of 1 min. 17 $\frac{3}{4}$ secs. The sensation of the meeting was, of course, the magnificent victory for Great Britain, secured by Mr. Clifford Earp, driving the now famous 6-cylinder Napier. It will be remembered that last year on Gaillon Hill-Climb the Napier firm gave a fore-taste of what they were likely to achieve with their new racer by running up the pick of the Continental vehicles so closely that a note of alarm was sounded throughout the French motor Press as to the probability of a British car ousting

the French vehicles from their record-holding position. At the time the Napier car had been completed only in time to enable it to get to the scene of action, and the consequently record work of this 6-cylinder car in America and Great Britain since fully justified the expectation which has now been realised of Mr. Edge's Napier car taking the lead on the Continent. We shall hope to see Mr. Clifford Earp repeat his triumph at Gaillon on the 15th, when we trust to see many of the crack racing machines in line with him, so that his success may be the greater to record, whilst we are hopeful of a further triumph for him in the meantime at Dourdan to-morrow, Sunday.

The times for the racers were only taken over the standing kilometre, as also for the tourist cars, from 25,000 francs down to 8,000 francs; the standing mile was the distance for the next two classes, whilst the flying

mile was reserved for motor bicycles and heavy vehicles. Altogether seven previous records for this hill were lowered, some of them very badly, notably Mr. Clifford Earp, on the 6-cylinder Napier, bringing Rigolly's 45½ secs. for the standing kilometre down to 38½ secs.

Racers (Standing Kilom.).

Heavy Cars, under 1,000 kilogs.—1. Clifford Earp, (6-cylinder Napier, Dunlop tyres), 38½s.; 2. Stead (Mercedes), 39½s.; 3. Faure (Mercedes), 46½s.; 4. Pierron (Mors), 53½s.; 5. Lapertot (Automoto) 1m. 7½s. Previous record: Rigolly 45½s.

Light Cars under 650 kilogs.—1. Hanriot (Darracq, Michelin tyres), 41½s. Previous record: Danjean, 50½s.

Voiturettes (under 400 kilogs.).—1. De la Touloubre (Darracq, Michelin tyres), 53½s.

Motor Bicycles (under 50 kilogs.).—1. Anzani (Alcyon), 55½s. Previous record: Lamberjack, 55½s.

Tri-Cars (½-litre).—1. Riviere (Moto-Tri Contal), 1m. 17½s.

Tourist Cars (over the Standing Kilom.).

CLASS I.—Over 25,000 francs.—1. A. Gardanne (Panhard - Levassor, Michelin tyres), 55½s.; 2. Graves (Mercedes Simplex), 1m. 0½s. Previous record: Gabriel, 56½s.

CLASS II.—18,000 to 25,000 francs.—1. Gasté (Radia, Michelin tyres), 1m. 4½s.; 2. Pelzer (Serpellet), 1m. 18½s.; 3. Quillard (Rochet - Schneider), 1m. 25½s. Previous record: Caillois, 1m. 32½s.

CLASS III.—15,000 to 18,000 francs.—1. Lemgruber (Fiat, Michelin tyres), 1m. 7½s.; 2. Marnia (Radia), 1m. 15½s.; 3. Gasté (Radia), 1m. 21½s.

CLASS IV.—12,000 to 15,000 francs.—1. Giry (Svelte), 1m. 40½s.; 2. De Salvert (De Salvert), 1m. 42½s.; 3. Ouzou (Florentia), 1m. 43½s.

CLASS V.—8,000 to 12,000 francs.—1. Chanliaud (Serpellet), 1m. 13½s.; 2. Baras (X.), 1m. 18½s.; 3. Deguingand (Vinot-Deguingand), 1m. 22½s. Previous record: Pelzer, 1m. 15½s.

Tri-Cars.

1. Vandelet (Stimula), 1m. 31s

Over the Standing Mile.

4,000 to 8,000 francs.—1. Delaunay (Boyer), 3m. 25½s.; 2. Demmer (Boyer), 3m. 39½s.; 3. Mionnet (Serpellet), 4m. 7½s.

Under 4,000 francs.—1. Gachet (Boyer), 5m. 30½s.; 2. Bailleau (Bailleau), 5m. 40½s.

Over the Flying Mile.

Motor Bicycles (½-litre).

1. Giuppone (Peugeot), 1m. 40½s.; 2. Anzani (Alcyon), 1m. 49½s.; 3. Contant (Quentin), 1m. 49½s. Previous record: Collomb (standing), 1m. 43½s.

Heavy Vehicles.

Ariès (wagon, 4,610 kilogs.), 17m. 20s.; Automoto (wagon, 1,220 kilogs.), 9m. 3½s.; Brillié (wagon, 8,270 kilogs.), 17m. 53½s.; Brillié (omnibus), 14m. 42½s.; Krieger (omnibus, 4,380 kilogs.), 17m. 3½s.

A COMPETITION for radiators is to be held in Paris during the present winter under the auspices of *L'Auto*, and it is hoped with the assistance of the A.C. de France.

THE competition for speed indicators in Germany arranged jointly by the Mitteleuropaischer Motorwagen-Verein and the Prussian Ministry, has been postponed until March 31st next year, the conditions remaining unaltered. This contest, being officially recognised by the Government, and likely, therefore, to have a far-reaching effect upon any selected instrument, should commend itself to the notice of English makers. All information can be obtained on application to the Secretary, Berlin W, 9, Linkstrasse 24, I.

MOTOR BOATING.

BURNHAM-ON-CROUCH MOTOR BOAT MEETING.—Burnham-on-Crouch from the sea and the Quay at Burnham. The Burnham Yacht Club may be distinguished by the bunting flying.

Burnham Meeting.—During three days of the last week of September, the British Motor Boat Club, by way of winding up the season, held an interesting race meeting at Burnham-on-Crouch. On the first day (Thursday, September 28th), the programme contained entries for a race for 40 ft., 35 ft., and 25 ft. boats, as well as another race for *bona fide* sea-going cruisers. In the 40 ft. class, over a 30-mile course, the Hon. J. Scott Montagu and Mr. Lionel de Rothschild's Napier II. won the *Motorist and Traveller* Cup in 1h. 36m. 16½s., Lord Howard de Walden's Napier being second in 1h. 58m. 31s. In the 35 ft. class, the 20-mile race was won by Mr. Mawdsley Brooke's Baby II., in 2h. 2m. 14½s.; Mr. Peyman's Pallas did not make good

time in this event owing to engine trouble, and she came in about twenty minutes after Baby II. In the 25 ft. class there were four entries, including the Sultan of Johore's Iblis, which attracted considerable attention. Mr. J. Stirling's Elgiva came home first in 1h. 31m. 16½s. for the 14 miles, but Mr. Miall Green's Takumono was the winner under the handicap allowance of 15m. 13s. Iblis was allowed 16m. 19s., and took 1h. 49m. 39½s. for the course. In the sea-going cruiser handicap Mr. A. Westmacott's St. Helena won the event, and Mr. S. F. Edge's Napier Major was second, by their handicap allowances, although Mr. H. Norfolk's Comet made the fastest time of 2h. 2m. 33½s. for the 17 miles.

BURNHAM-ON-CROUCH MOTOR BOAT MEETING.—“Napier II.” making a flying start.

Friday's racing was continued under the same favourable weather conditions as prevailed on the Thursday. In the 40 ft. handicap, Napier II. was again successful, accomplishing the 30 miles in 1h. 47m. 47 $\frac{2}{3}$ s., Napier being second, with the running time of 1h. 59m. 52s. The next handicap was for 30 ft. boats over a 20-mile course, and in this event Mr. A. G. Fentiman's Javelin was victorious, with the running time of 2h. 13m. 29 $\frac{3}{8}$ s.,

The principal day of the meeting was the last (Saturday), when the “flying mile” championship was on the programme. Only two competitors started, and, for the third time at this meeting, Napier II. was victorious, although her time for the knot, of 2m. 15 $\frac{3}{8}$ s., does not count as a record, as it was made only in one direction, and that with the tide. Napier, the only other competitor, ran over the same course in 2m. 58 $\frac{1}{8}$ s.

BURNHAM-ON-CROUCH MOTOR BOAT MEETING.—“Napier” passing the Committee boat, with a flying start.

Baby II. being second, in 2h. 14m. 24s. actual time. The 25-ft. handicap results are:—

Distance—14 miles.		Actual Time.		Handicap Allowance.	
		h. m. s.		m. s.	
1. Mr. Miall Green's Takumono	1 41 49 $\frac{1}{2}$...	12 25	
2. Sultan of Johore's Iblis	2 3 44 $\frac{1}{2}$...	24 22	
3. Mr. L. Miles' Stirling	1 53 14 $\frac{1}{2}$...	10 12	
4. Mr. J. E. Matthew's Maya	2 42 50	...	34 40	

In the 30 ft. handicap, Baby II. covered the 14-mile course in 1h. 15m. 36 $\frac{3}{8}$ s., and won the event from scratch. With their handicap allowances Iblis took second place in 1h. 43m. 49s., and Javelin third in 1h. 22m. 28 $\frac{3}{8}$ s.

In the 40 ft. handicap, Napier II. unfortunately broke down, and Napier won the event by completing the 30-mile course in 1h. 43m. 54 $\frac{1}{8}$ s.

BURNHAM-ON-CROUCH MOTOR BOAT MEETING.—“Baby Brooke” crosses the starting line.

The Committee boat. As seen from "Napier Major." Capt. Evans, who was in charge of this boat in its recent lengthy voyage round the coast, is standing on the left.

Interested spectators on "Napier Major" and the Committee boat.

BURNHAM-ON-CROUCH MOTOR BOAT MEETING.

THE Admiralty continues to bestow attention on the application of the motor boat to naval purposes. The Dreadnought is to be fitted with motor-propelled packet boats, in place of the usual steam pinnaces. Estimates have been obtained for two 50-ft. motor launches for the vessel, which it is expected will prove more economical than the steam pinnaces hitherto employed. The Admiralty are conducting further experiments by replacing the engine of a steam launch by an internal combustion motor, with a view to ascertaining the suitability and reliability of engines of this kind in rough weather. The Admiralty will, no doubt, seriously consider the replacement of steam pinnaces by motor-driven boats throughout the navy, should their experiments warrant the change.

MOST people who are interested in motor boating will recollect the contention of Madame Du Gast that she was entitled to the Mediterranean Cup, as her boat got nearer to the goal than any of the others *before it had to be abandoned*. A similar claim has now been put forward by a humorous French journalist on behalf of the Mercedes boat, which took part in the race, on the following somewhat novel ground:—Recent soundings have established that of all the boats which went down in that unfortunate race, the Mercedes lies much the deepest, being, it is stated, 1,850 metres below the surface, the next best in this particular line being only 1,600 metres down. Therefore, Mercedes, it is claimed, reached the farthest point!

Mr. R. B. Robinson, the secretary of the Motor Yacht Club, watching the races.

Mr. Robinson and the officers recording the performances.

BURNHAM-ON-CROUCH MOTOR BOAT MEETING.

HITHERTO there have been hotel proprietors who have not been altogether in favour of automobilists as guests, but prejudice of this description is diminishing, and the motor-car traveller is now universally being welcomed and treated with consideration and confidence. A good example of this is provided by the experiences of an American automobilist who had come over from France and had nothing but French bills in his possession, and without thinking about the matter, found that he was unable either to buy petrol or pay his hotel bill. He

made this discovery at the Royal Star Hotel, Maidstone, where the landlord not only agreed to lend him what money he required, but refused to listen to the suggestion that he should retain the French bills as security until the amount could be returned. It is some evidence at any rate of the general character for honourable reliability which motorists are establishing in this country, and it is certainly an occurrence which should induce all motor-car owners to hold the Royal Star Hotel, of Maidstone, in special favour for the future.

MOTOR CYCLING.

Auto-Cycle Club Race Meeting.—At the Crystal Palace track on Saturday afternoon several enthusiastic racing motor cyclists competed in what is the only track event of the year solely confined to their particular sport. There were three principal items on the programme, and also what might be called an "extra turn" by Mr. G. A. Barnes, who gave a 2-mile exhibition ride on his 4-h.p. racer, which was too big to be entered for any of the other events.

The first of the contests was for the AUTOMOTOR JOURNAL Cup, which is held by the rider making the fastest time for the flying mile. It is a humane but exceptionally monotonous type of event, for each competitor was despatched separately, and his performance—except where varied by faulty ignition or the discovery that the petrol tap was turned off—was entirely devoid of spectacular interest. In this event H. V. Colver secured first place with 1m. 11s. for the mile, this being 4 secs. better than C. R. Collier's time of last year.

A five miles handicap, run in heats, for the *Motor Car Journal* Challenge Cup was the next item, and this proved a more exciting event. Each heat made a good race, H. V. Colver, Rene Thomas, and W. Hodgkinson proving the respective winners. In the final, W. Hodgkinson, with 7 secs. start, won the event. Rene Thomas, the French rider who recently made record times in Paris on an Alcyon machine, a similar make of bicycle to the one he rode on Saturday, was second after starting from scratch.

The One-Hour Scratch Race for the *Motor Cycle* Challenge Cup was principally remarkable for the continued excellence of Thomas' performance, who covered 45 miles in the hour—a distance of over two miles in excess of the previous best on that track. In the first thirty minutes he covered 22½ miles, 30 miles were finished in 40m. 2s., and 40 miles in 53m. 17½s.

From very few points of view could the meeting be called particularly interesting—towards the end it was decidedly slow, and it is little wonder that the long-suffering spectators grew impatient waiting in the chill wind on such a dull day. Happily, however, the track was not spoilt as it was last year, by a downfall of rain, for, although threatening, the weather was not actually wet. Under the direction of Mr. H. Godfrey, the Crystal Palace Military Band performed in the ring during the afternoon. According to the programme, they presumably played an attractive series of selections; but, unfortunately, their efforts to please were rendered entirely futile by the unceasing noise of the machines, and it was absolutely impossible to hear a note—yet they gallantly went on playing!

The following is a tabulated list of results:—

Flying Mile.—AUTOMOTOR JOURNAL CUP.

m. s.		m. s.	
H. V. Colver (Matchless)	1 11	C. R. Collier (Matchless)	1 17½
W. Hodgkinson (J. A. P.)	1 12½	E. Varney (Crownfield)	1 17½
W. W. Genn (Minerva)	1 15	C. Read (New Century)	1 21½

Five Miles Handicap.—MOTOR CAR JOURNAL CUP.

Heat 1.—H. V. Colver (Minerva) (5 secs. start), 6m. 27s.

Heat 2.—Rene Thomas (Alcyon) (scratch), 6m. 17½s.

Heat 3.—W. Hodgkinson (J. A. P.) (7 secs. start), 6m. 23½s.

Final.—1st, W. Hodgkinson (J. A. P.) (7 secs. start), 6m. 9½s.; 2nd, Rene Thomas (Alcyon) (scratch), 6m. 7½s.

Note:—Net running times only are given above.

One Hour Scratch Race.—MOTOR CYCLE CHALLENGE CUP.

1st, Rene Thomas (Alcyon), 45 miles 146 yds; 2nd, J. F. Crundal (Humber), 41 miles 1,376 yds.; 3rd, H. V. Colver (Matchless), 40 miles 400 yds.

Law as she is Expounded.—We have often wondered what might be the mental diet with which Petty Sessional magistrates regaled themselves, and which was accordingly responsible for the noteworthy decisions at which they arrive. Now we have solved the problem, at any rate in part. There is a periodical entitled *The Justice of the Peace*, and presumably it is published for and read by the confraternity of the Great Unpaid. The current number devotes an article to the subject of "The Motorist and the Law," and from this we learn:—

It must be clearly understood that the basis of the rights and duties of the motorist and the public with regard to the user of the highway is to be sought in principles of the common law and not in the provisions of any statute.

Two Mile Exhibition Ride.

G. A. Barnes (4-h.p. Barnes), 1 mile in 1m. 8½s.; 2 miles in 2m. 18½s.

Portmarnock Speed Trials.—The last of the season's speed trials, under the auspices of the Dublin Centre of the Motor Cycle Union of Ireland, were brought to a successful issue on Saturday last. The meeting was at Portmarnock, where the sand was at its best, and a strong wind which came from the Malabede end, favoured the competitors, some of whom succeeded in reducing the record for the mile. The programme was made up of four events, the principal item being a one mile scratch open for the Wheatley Bowl, presented to the Irish Automobile Club by the firm of that name, and won by C. B. Franklin at the speed trials last year. A mile novice, a mile members' handicap, and a ten miles handicap made up the card. A committee, Messrs. T. W. Murphy, D. P. Robinson, and the hon. sec., G. Mague, arranged the handicaps. A. Parker was first to finish in the ten miles handicap, but was disqualified for pedalling beyond the fifty yards flag, and for not dismounting at each end of the course.

Results.

Mile (Novices).—1. T. C. Brown, 2-h.p. Sanspareil, 20 secs. start; 2. W. Jacques, 3-h.p. Alcyon (scratch). Winner's nett time, 1m. 49½ secs.

Mile (Members) Handicap.—Final:—1. A. Parker, 2½-h.p. Minerva, 25 secs. start; 2. S. Black, 2-h.p. Triumph, 35 secs. start; 3. W. Jacques, 3-h.p. Alcyon, 15 secs. start. Winner's nett time, 1m. 27½s (Irish record).

One Mile Scratch (Open), Wheatley Bowl.—Final:—1. C. B. Franklin (holder), 6-h.p. J.A.P.; 2. J. G. Drury, 3-h.p. Triumph. Won easily; time, 1m. 17½s. (Irish record).

Ten Miles (Members) Handicap.—1. C. G. H. Lewis, 2½-h.p. F.N., 2m. 20s. start, nett time, 19m. 2s.; 2. C. B. Franklin, 2½-h.p. F.N., scratch, nett time, 17m. 27s.; 3. H. Mooney, 2½-h.p. F.N.

Hydra Cup.—In regard to the question which arose in Paris as to Cissac being entitled to claim the Hydra Cup by reason of his having created new records for the 100 kiloms., it has been decided by the committee who interpret the rules of the Cup, that although his new times are recognised as world's records, the Cup is to be held by Thomas, as Cissac did not comply with the rules by giving the necessary notice of his intention to challenge for the Cup.

International Cup.—In regard to the suggestion made by the Motor Cyclists' Union of the Austrian A.C., that the machines should be weighed without their tyres in future for this contest, they now suggest that such weight, without tyres, should be fixed at 47 kilogs., this weight to include magneto. A second proposition made by Mr. Klement, of Laurin-Klement, is that only the weight of the motor should be fixed, the weight of the rest of the machine being naturally and necessarily regulated automatically by this method. These and other suggestions are to be considered by the International Congress, which will be held in Paris in December.

UNDER arrangements made by the Auto Cycle Club, members are now entitled to take their machines into France free of duty, on production of their card of membership.

The right of each member of the public to the uninterrupted user of the highway has been prescribed by no statute. It is an inherent right, the existence and recognition of which is, in all probability, coeval with the existence of the highways themselves.

If anyone will take the trouble to turn up the Highways Act of 1835 they will see that the rights of the public and of anybody driving vehicles on the high road are very clearly and distinctly defined by that statute. If this is the kind of thing that a periodical presumably designed for the enlightenment of our magistrates puts before them in regard to the motor car and vehicle question, the strange decisions at which they frequently arrive are not greatly to be wondered at.

Motor vans for commercial purposes are daily being brought more into requisition throughout the country. Messrs. De Dion-Bouton, for the past three years, have been themselves running one of their own vans in London in connection with their business. We give a photograph of this vehicle above, both of the van itself and one showing the remarkable holding capacity of the body, no less than 8 men being able to seat themselves inside. This space has mainly been secured by placing the motor under the seat of the driver, the cubic capacity being about 100 feet.

CLUBS AND ASSOCIATIONS.

Aero Club.—The meeting of the club at Reading to-day, Saturday, has been cancelled, and in place of this the committee have arranged an ascent at Pitmaston Park, Moor Green, Birmingham, in response to Sir John Holder's invitation. The ascent will take place at 1.30 p.m.

Automobile and Cycle Engineers' Institute.—The first ordinary meeting of the session 1905-6 will be held on October 26th at the Grand Hotel, Birmingham. At this meeting the president for the year, Mr. Alex. E. Tucker, F.I.C., will deliver his presidential address, which will take the form of a paper on "Vanadium Steel for Motor Construction."

Blackheath A.C.—The final run of the season takes place next Saturday, October 14th, when the outing will be to the Bull Hotel, Chislehurst. At this meeting-place, occasion will be taken to present the prizes which were won at the Hill Climb on July 8th, and at the Gymkhana on September 2nd, these functions being followed by an informal concert.

Nottinghamshire A.C.—Last week, in response to the invitation of Mr. F. A. Smith, about seventy members and friends drove over to Cole Orton Hall. The visit was one of those especially calculated to further the interests of the club from the social side, and the hospitable reception which the members received made a strong impression in this respect. Mr. Charles Hardy, the president of the club, voiced the feelings of the members in a very hearty vote of thanks to the host and hostess. This was seconded by Mr. Booth Grainger, the secretary, who reminded the members and their friends that the outing was the direct outcome of the abandonment of the Buxton meeting, which was cancelled as a protest against the magisterial decision in an alleged furious driving case.

West Surrey A.C.—The last meet of the season, and one of the best attended hitherto, took place on the 30th ult., at St. Mary's, Godalming, the residence of Mr. R. Buttemer, hon. secretary of the club, about 17 cars being present, with over 70 members and friends. Among the members were: Mr. Barker (Cupelle), Dr. Bryden (10-h.p. Argyll), Mr. R. Crothers (9-h.p. Darracq),

Col. Fairtlough (12-h.p. Darracq), Mr. Fletcher (20-h.p. Durkopp), Dr. Hall (9-h.p. Clement), Dr. Henderson (20-h.p. Dennis), Mr. Houghton, Mr. Ingram (15-h.p. C.G.V.), Major Matson (10-h.p. Renault), Mr. Ponsford (8-h.p. Clement), Mrs. Sartorius (Cadillac), Mr. Vogan (24-h.p. Simms-Welbeck), Mr. Warne, Mrs. Bullard (20-h.p. Dennis), Mrs. Williams and Mr. F. Williams (Martini), Mr. Wrigley (12-h.p. Clement), Mrs. Rideal (Benz), while the other guests included Lady Caroline Grenville, the Misses Hadaway, Col. and Mrs. Pollock, and Mrs. Keightley.

New Automobile Clubs.—A club is being formed for the county borough of York and district, including Malton and Scarborough, under the auspices of the Yorkshire A.C. and the Motor Union. Already an influential provisional committee has been formed.

In Essex steps have also been taken by the Motor Union to form a county club. On the provisional committee for this body the Earl of Warwick has consented to serve, and immediately a full and strong provisional committee has been got together, a meeting of the leading automobilists of the county will be convened by the Union at Chelmsford. Automobilists in the county of Essex should at once communicate with the secretary at 19, Down Street, Piccadilly, W.

Mercedes 1906 Innovations.—Referring to our article describing the new 70-h.p. Mercedes car—which is to be the 1906 edition of the well-known 60-h.p. model—the Speedwell Motor Company write pointing out that their cars also have the necessary provisions made for holding the starting-handle in a vertical position, when not in use. This useful arrangement, in one form or another, is, of course, by no means a novelty; the Speedwell cars have, we learn, had it for no less than three years, and we have, ourselves, often noticed it on other makes of vehicle as well. Being one of those minor details which are so much appreciated by all practical motorists, it will doubtless be adopted even more widely in the near future.

CORRESPONDENCE.

* * *The name and address of the writer (not necessarily for publication) MUST in all cases accompany letters intended for insertion, or containing queries.*

THE BUCKDEN POLICE TRAP.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—So much unfavourable notoriety has been attracted for some months past by the methods of the St. Neots county magistrates, that the annexed copy of a communication we have to-day addressed to their clerk may interest such of your readers as have been victimised by this glaringly unfair trap.

To avoid the necessity of complying with the requirements of the Act in relation to charges for exceeding the speed-limit under Section 9, the Head Constable of Huntingdonshire, acting under some understanding with the Bench (and we have good authority for saying this), has for some time made it his invariable practice to charge all motorists who fall into his clutches with driving to the public danger under Section 1. Conviction follows in each case with the consequent endorsement of the licence, and the object of the proposed appeal is to obtain a decision of the High Court on the important question whether magistrates are justified in convicting for driving to the public danger, without any evidence of actual or possible danger to the public beyond the statement of a couple of country policemen and a carefully-prompted village schoolboy that, in their opinion, the car was being driven at a dangerous speed within the meaning of Section 1.

The Legislature has seen fit to impose a speed limit with penalties for exceeding it, but it was not, we contend, the intention that a skilled and careful driver, with his car under perfect control, driving at the rate (accepting the police timing) of 21 miles an hour through a deserted village street in broad daylight, should be convicted on the far more serious charge of driving to the public danger.

Until, however, a ruling of the High Court is pronounced to this effect, the enlightened Solomons of St. Neots will doubtless continue, without discrimination, to penalise and endorse the licences of the most cautious and considerate drivers, against whom the only real recklessness that can be shown is that they have had the temerity to pass through the district at all.

Yours faithfully,
MELLOR AND CO.

September 27th.

[Enclosure.]

The Clerk to the Magistrates for the County of Huntingdon,
The Petty Sessional Court House, St. Neots.

SIR,—*Re* William Horace Robinson. In this case, in which, on Thursday last the 21st inst., the magistrates for the County of Huntingdon, on evidence which can only be described as farcical, convicted the above-named defendant, under Section I of the Motor Car Act, we are instructed to take the opinion of the High Court of Justice on the question of law, whether there was any evidence of public danger before the Bench, on which the conviction could be justified under the Section in question. In our opinion, there was an entire absence of any such evidence, and we have accordingly to apply, and do hereby apply, on behalf of the defendant, to the magistrates to state a special case for the opinion of the High Court, setting forth the facts of the case and the grounds on which the conviction is questioned. Should the magistrates refuse to do so, we have advised an application for a mandamus to compel them, as the case is one on which we feel strongly that a gross injustice has been committed.

We hope, however, that the magistrates will not think it necessary to require this additional expense to be incurred, seeing the general importance of the questions involved, and the excessive hardship already inflicted on this particular defendant, whose wage-earning capacity as a professional driver will be permanently reduced if the conviction is confirmed.

Please send us a copy of the depositions, for which we will pay the regular charge.

We are,
Yours faithfully,
(Signed) MELLOR AND CO.

September 27th.

BRAKES ON MOTOR CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—*Re* a useful but not often used brake on a motor car. The above heading refers to the very excellent natural brake that all motor cars possess, but which few cars are designed to use, or the drivers do not use, namely the engine itself with the ignition switched off.

I have been carefully carrying out some experiments in the past few months on my car, using it with the clutch only connected up

to the clutch-pedal, so that when I wished to put on the foot-brake, the foot-brake pedal only was used, and in no way interfered with the clutch-pedal, and again, if I wished to use the side-brake, this could be applied without disconnecting the clutch.

The result of so using my Napier car for the past few months has so completely converted me to this system that I thought it would be interesting to write to a large number of users of motor cars and hear what their opinion was; in most instances I have had replies, many of which show very great and careful consideration of the subject.

The nett result of the replies were 6 per cent. in favour of the clutch and foot-pedal brake being connected up together, so that when the foot-brake is put on the engine is disconnected, and the use of what seems to me a very useful and effective brake is thus lost.

Fifty-nine per cent. prefer to have the clutch entirely independent of either foot or hand-brake, and I think it is very interesting to note that such a large number as 59 per cent. should have departed of their own initiative from the ordinary manufacturing practice and found what I think is the best system.

The balance of 35 per cent. like the hand-brake to withdraw the clutch.

The matter is, I think, one of very great interest to automobilists and could with advantage be ventilated in your columns.

Even though the system of having both brakes disconnected from the clutch might occasionally cause inconvenience, I think myself that the great reduction of wear and tear on brake parts would more than compensate for any such slight inconvenience.

Yours truly,
S. F. EDGE.

September 27th.

GREAT BRITAIN AND AUTOMOBILES.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I am very pleased indeed to see from the leading article in your issue of September 30th that at last it is clearly recognised that Great Britain is the greatest automobile consumer in the world.

You may remember that I drew particular attention to this fact in a speech I made at a luncheon given by the Society of Motor Manufacturers and Traders in July, 1902, and again at a dinner at the Trocadero Restaurant on Friday, October 16th, 1903, besides, of course, many references in letters and articles from time to time in the Press.

I have had few supporters in this view that I have taken, but it is very gratifying to at last find that the French Press and the French industry have at last realised that Great Britain is the true centre of the automobile world. This may be unpleasant reading for some of the agents over here for French cars, who, properly from their point of view, have tried to belittle Great Britain and have held France up as everything that is perfect in automobilism, but Mr. George Prade in the French Press has clearly shown the true state of affairs, and there is no doubt that to-day with British cars holding the world's speed record, and the world's reliability test, besides their reputation for general excellence and workmanship which thousands of British users of British cars can testify to, the foreign manufacturer must very rapidly now see that his only market will shortly be in his own country. Then, as soon as the British manufacturers have been able to fill the home demand then will the time come for the exporting of British motor cars to all parts of the world, and by this time it will be purely on merit, no favour will be required.

Yours truly,
S. F. EDGE.

September 30th.

NON-SKID AND TYRE PROTECTION.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—It would appear from recent queries in the Press, and also from information which comes out in the course of business, that the non-skid is very much over-rated as a tyre preserver.

The chief objection to a non-skid is its frictional contact with, and, therefore, wear upon, the tread of the tyre. This objection is a serious one, as we happen to know from observations made to us by people who from time to time send to our repairs department covers badly chafed and worn through constant friction with the non-skids, which have been applied in permanent or detachable form. And in this connection we are rather of opinion that a detachable non-skid is infinitely less injurious to the tread of a tyre than one making a permanent fixture, inasmuch as the acid needed to make the latter firmly adhere is a serious source of decay. All

Trusting that with your usual courtesy you will allow this letter to appear in your next issue,

Yours faithfully,
HARVEY FROST AND CO., LIMITED,
H. HARVEY FROST,
Managing Director.

Amongst the splendid trophies which have been secured on the Continent by the De Dietrich firm with their well-known cars, is the Pyrenees Cup for Touring Vehicles, which was recently won by them with a 40-h.p. car driven by Mr. Sorel, particulars of which event we recently recorded in our pages. We are enabled to give a reproduction above of this beautiful work of art. The Pyrenees competition, for which 80 cars started from Toulouse, it will be remembered, was over a distance of 1,385 kiloms., the major part of which included very severe hill-climbing.

Decorated motor cars are now generally a striking feature of carnivals and processions in aid of charities, &c. Recently a demonstration was arranged in connection with the Cottage Hospital at Bexley Heath, when one of the most admired vehicles in the whole procession was the above 12-h.p. Siddeley Car, which moreover succeeded in collecting the highest amount in aid of the Hospital's funds.

THERE is one class of the community, not motorists themselves, who are friendly to the automobile movement for a very peculiar reason. In old days the cyclist, no matter practically at what speed he rode, was the special victim of the policeman. He was haled before local benches of magistrates, principally at Reigate, and charged with furiously driving his rubber and iron steed. Since the advent of the motor car and the elaborate arrangements involved in the usual police trap there has been a "closed season" for cyclists, and it is quite unusual now to hear of their appearance on this charge at police courts. They recognise their indebtedness to the automobile, and, as one of them in a letter to the *Daily News* points out, "cyclists gratefully decline to offer serious opposition to the progress of motoring, which has delivered them from police persecution."

SOME two years ago we described how the Bishop of Milan was in the habit of carrying out his diocesan visitations per motor car, and how he was enabled in this way to cover a stretch of country which it would have been impossible even to tap but for this means of conveyance. The example of the Bishop of Milan is now, amongst other dignitaries of the

being followed by the Bishop of Liverpool, who is providing him with a 24-h.p. which he will in future circumnavigate top down on out-of-the-way rural deans, rectors when they least expect it. The tool is a great worker, and there is no automobile will enable him to do even more than he hitherto has done, and no parochial clergy will thoroughly enjoy the effect of being visited by their Bishop in meditation when they least anti-

NCH inventor claims that he has produced an appliance which will in future obviate necessity for motor car drivers improving their physiognomies with goggles, and will enable the public to admire what he is pleased to term the "coquettish harmony of feminine coiffures." The arrangement, however, is nothing very epoch-making. It consists of a transparent screen of glass or gelatine of the ordinary kind raised by special means about three feet above the bonnet, but brought much further back than usual, being connected to the top of the bonnet by leather or other flexible material. It would seem that this device must largely spoil the appearance of the car to which it is fitted, and we do think that the supposed advantages would adequately compensate for this.

Within the next six months, the Central Motor Car Company expect to place 200 motor cabs—similar to that shown above—in public service in the Metropolis, on behalf of the London Automobile Cab Company. Our photograph shows one which is now being driven in town by a London cabman, who, a couple of weeks ago, was plying his trade with an ordinary hansom. The "Ford" Cab is of the live-axle type, is propelled by a 20-h.p. four-cylinder vertical engine, and has a two-speed gear of the epicyclic variety. Amongst some of the special claims which are made for it are that it is quite silent, that no changing of speed is necessary under ordinary running conditions—since the speed can be varied from 4 to 30 miles per hour on the top gear—that the engine can be started from the seat ("on the switch"), and that the cab will turn right round in a 26 ft. 6 in. roadway; the wheel-base is 7 ft. 8 in., and the track 4 ft. 8 in. These self-propelled hackney carriages—which have a roomy landaulette type of body—are to be fitted with Taximeters.

MR. WILLIAM RICH has been appointed Lieutenant in the Motor Volunteer Corps.

A REMARKABLE accident happened recently at Lordship Park, when a motor tricar ran into the front wheel of a horse-drawn 'bus. The 'bus wheel was smashed

and so was that of the tricar, but the tricar propped the 'bus wheel up, and so nobody was hurt.

MR. CATHCART WASON, who we believe represents the Orkney Islands, will presumably be painfully affected by the intelligence that another motor omnibus has been landed at Kirkwall for public service in the Islands.

Railway motor coaches are now becoming extensively used throughout the country, and, as we have always anticipated, are proving extremely successful, and should result in substantial gains to the various companies who, in conjunction with road motor vehicles, are extending their traffic in this very up-to-date and useful direction. The above is one of the latest self-contained steam coaches, put on by the London and North-Western Railway Company on their North-Wales line between Prestatyn and Dyserth. The engine is enclosed within the body of the car, and the engine-bogie is specially constructed for carrying the engine and boiler in addition to one end of the car body. The latter is attached to the bogie by a cast-steel centre casting resting on the bogie bolster, and if at any time it is desired to remove the engine and boiler for repairs, it is only necessary to raise the engine end of the car sufficiently high to disengage the centre casting, so that the bogie with the engine and boiler can be drawn from under the car through the doors at the front end. Another bogie with engine and boiler complete can then be put in its place. In this way there is no necessity for the coach to be withdrawn from traffic on account of repairs to the engine. The weight of the entire carriage, when the tanks and boilers are full, is 43 tons 8 cwt. The wheels are 3 ft. 9 in. diameter on the tread. The engines can be worked from either end of the car, and the lighting is by electricity throughout. Electric bells are provided and also speaking tubes, so that the driver, fireman, and conductor are all in communication with one another. The passenger compartments are heated by a simple system.

ALL good motorists recognise that it is their duty to repress reckless driving and abuse of the high roads on the part of their colleagues, and Earl Russell is accordingly to be congratulated upon prosecuting an especially flagrant offender who, late one evening, careered along through the village of Cobham at, it was stated, at least 35 miles an hour, and in the most reckless manner. The offender was ultimately fined £10 and costs, and the Bench thanked Earl Russell for his action. It is this kind of reckless driving that should be stopped, and other motorists should attempt to stop it. They are better qualified for doing so than the police, for they are not likely to be prejudiced, and they are in a position to judge adequately of speed and reasonable driving.

No doubt Earl Russell acted with the best intentions and in the public interest, and was animated by the feeling which actuates every self-respecting motorist—detestation of that greatest enemy of the movement, the reckless driver. Lord Russell's position is to some extent exceptional, but in general perhaps it would be as well when other motorists desire to act in the same way—as we hope they will when a flagrant case of this kind comes

before their notice—if instead of acting independently, they would bring the matter before the Automobile Club and arrange for the proceedings to be undertaken by that body. We suggest this for the simple reason that the moral effect produced would be so very noticeably greater.

A NEW terror—to evil-doers—is about to be added to Paris in the shape of a corps of motoring policemen, which will consist of 200 members, and whose principal business it will be to see that no infringements of the law are perpetrated by automobilists and motor cyclists in the French capital. The 200 will constitute, it may well be said, a *corps d'élite*, as before they are admitted they will be subjected to a severe examination by an examiner, who will throw all sorts of obstacles (stuffed figures of old women, babies, and the like) in their way as they drive along, expecting them to dodge them with facility. In addition, the members of the corps are required to be expert mechanics. On the whole, however, the motorist will probably far prefer dealings with automobilist policemen than with the "magistrates' highwaymen," as Mr. Coleridge has dubbed them, such as we have in this country.

NEW COMPANIES REGISTERED.

[Taking powers to manufacture or deal in motors, motor cars, or accessories, either as their principal or part of their objects.]

Automobile Log Syndicate (Limited), 11, Queen Victoria Street, E.C.—Capital, £5,000 in £1 shares. Object, to adopt an agreement with H. Soar, and to acquire a certain invention.

Chassis (Limited), 4, Broad Street Place, E.C.—Capital, £5,000 in £1 shares. Object, to carry on the business of motor car, omnibus, &c., proprietors, manufacturers, and dealers, &c.

Gnome Motor Car Company (Limited), 66, Great Russell Street, W.C.—Capital, £5,000 in 4,750 ordinary shares of £1 each, and 5,000 deferred shares of 1s. each. First directors, Lewis J. Levi and Lionel J. Levi.

Laws Stores (Limited).—Capital, £2,000 in £1 shares. Object, to acquire the business carried on at 13, Liverpool Street, and 215, North Road, Preston, Lancashire, as Laws Cycle Stores, manufacturers, gasfitters, dealers in cycle and motor parts and accessories, gasfittings, &c. J. Law is first director.

New Arrol-Johnston Car Company (Limited), Underwood Road, Paisley.—Capital, £100,000 in £10 shares. First directors: W. Beardmore, J. Hunter, and J. S. Napier (Scotch Co.).

Newport (Mon.) Motor Supply and Garage (Limited), Cambrian Chambers, Cambrian Road, Newport, Mon.—Capital, £3,000 in £1 shares. First directors: J. M. Griffiths, E. M. Linton, C. D. Phillips, and P. Powell.

IN connection with the affairs of the Automobile Corporation, Limited, which were before the Court of Bankruptcy under the winding up order recently made against the company, it transpired at the meeting of creditors that the company formed in February,

1905, had a capital of £1,000 to carry on company promoting business, Mr. Edgar Antrobus Mackenzie being the vendor, promoter, and practically the only shareholder and debenture holder. The Corporation unsuccessfully attempted in April last to float the Herne Bay and Canterbury Motor Service Company, Limited, but the public in no way responded to the invitation. Other matters unconnected with automobilism were exploited, which have been the cause of the company's non-success, but the chief reason of failure is attributed to the collapse of the Herne Bay issue.

COMMERCIAL POINTS.

Harvey Frost and Co., Ltd., favoured by the War Office.—For some little time an H. F. Vulcaniser has been subjected to a variety of tests by the War Office, with a result most gratifying to the patentees and manufacturers, who have received a Government contract for an additional supply of H.F. Vulcanisers, including "Standards" and "Re-Treaders." The Chief Inspector of Mechanical Transport recently visited 39, Great Eastern Street, and witnessed a variety of demonstrations in tyre repairing by the H.F. process, and was so greatly struck by the high quality of work attained, and the high efficiency of the H.F. appliances generally, that he at once requested the firm to tender for an additional number of these machines. This mark of Government patronage is the more satisfactory for the fact that the H.F. appliances were fully tested by the War Office before the contract was given.

A GRAND PRIX has been awarded at the Liege Exhibition to the well-known "Sternol" brand of lubricating specialties for motor cars.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.L.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

21275. 4th October, 1904. A New or Improved Petroleum Engine. Robert O. Allsop, 37, Norfolk Street, Strand, London. This engine has two motor cylinders and one fuel vapour pump. The pump serves the two Otto cycle motor cylinders alternately with vapour of petroleum, and the petroleum may be more or less gasified by adiabatic air compression in the pump according to the setting and arrangement of the valves and valve-operating gear. The pump piston on its outstroke draws in a charge of hydrocarbon sprayed with air; on the instroke the charge is compressed, and at a suitable point in the instroke the opening of a valve allows the vapour or gaseous mixture to be discharged into

FIG. 2.

one or other of the motor cylinders. The crank pins of the two motor pistons work together, and the crank pin of the pump piston is set at 180 degrees relatively to the crank pins of the motor pistons. There are two figures. Fig. 2 is a section of the pump, which is placed between the two motor cylinders. C is the pump cylinder, bolted to the centre of the crank chamber. G is the pump piston. The "half-time" or "two-to-one" gear wheels communicate rotary motion to the side shaft, S, on which are placed the cams which by means of tappets operate the exhaust valves of the motor cylinders and the gas or vapour valves, X. Z is a

cored casting forming the vapour superheater; 2 is an exhaust pipe; 3, a gas or vapour pipe; 4, air inlets to motor cylinders; 5, inlet valve to pump; the petroleum passes through a small hole in seating of valve, and is sprayed by the rush of air through the air passage, 7. At 8 is shown a cored casting heated by the exhaust products passing through passages, 9. The cored casting has a heated cone on to which the petroleum is sprayed. Copper baffle-plates, 10 to 10, secured by copper studs, 11, are connected to the cored casting or vaporiser. The central cone or funnel-shaped portion of the cored casting or vaporiser forms part of the clearance space of the pump. The vaporiser connects, and is suitably bolted to the pump and pump inlet valve. The pump piston on its out or downward stroke draws in air and sprays petroleum on to the heated cone and baffle-plates. The charge of vapour and air is on the following upstroke of the pump piston delivered into one or other of the motor cylinders according to the setting of the valve-operating gear. September 13th, 1905.

Fig. 1.

24905. 15th November, 1904. Improvements in or relating to Explosion Engines and the transmission of power therefrom. Friedrich A. Haselwander, Rastatt, Baden, Germany. This invention relates to an air pressure transmission from the internal combustion engine through a compressor and air pressure motor to the road wheels. In two-stroke-cycle engines the compressing of the air is an essential point, and the engine, therefore, contains a compressor or is coupled to such a compressor in which the degree of compression need only be so far increased that an air pressure motor can be driven with a satisfactory degree of efficiency, and that then the expanded exhaust from the same may serve as the scavenging air for the two-stroke-cycle engine with higher compression of the scavenging air and of an air pressure motor, the latter serving as the equivalent for the change-speed driving gear, and, if necessary, for the differential device. There are two figures. Fig. 1 illustrates the arrangement diagrammatically. The usual cycle of operations in

a two-stroke-cycle engine takes place in the space, *v*, in cylinder, *s*, above the piston, *k*; the exhaust, takes place through *a*, and the inflow of scavenging air takes place through opening, *e*, both of which openings are controlled by the piston. In the lower part, *p*, of the cylinder the scavenging air is sucked in through the valve, *s*, the compression takes place in the cylinder, and the sufficiently highly compressed scavenging air is forced out through the valve, *s*, through the passage, *h*, to receiving chamber, *r*, passage, *h*, to air pressure motor, *m* (here a turbine motor or rotary motor), in which the scavenging air working as the pressure air becomes expanded, and then at a lower pressure sufficient for the scavenging of the cylinder of the two-stroke-cycle engine, passes through passage, *h*, receiver, *r*, and passage *h*, to the air inlet of the two-stroke-cycle cylinder. In the air pressure motor regulation may be effected by alterations in the admission or by throttling in front of or behind the motor. A bypass pipe, *h*, with a throttle, *d*, may be fitted to convey the air past the motor, *m*, and direct to the receiver, *r*, to supply the combustion in the engine. September 13th, 1905.

PASSING EVENTS.

Much Misconception.

IN addition to his other admirable services to the automobile cause, Mr. Stenson Cooke, the secretary and protagonist of the Automobile Association, can lay claim to the *recherché* distinction of possessing a very fine sense of humour and a delicate pen with which to support it. One of the Surrey papers, representing presumably the interests which indirectly subsist on the fines raked in as the output of police traps, has been very angry with the arrangements which the Automobile Association has made by means of a corps of cyclists, scouts, and others, to keep motorists from breaking the law. Those good people who are infected with the anti-automobile *virus*, seem to regard it as quite a crime to warn motorists of unintentional excesses of speed when it so happens that policemen are ambushed on the roadside and ready to pounce. Mr. Stenson Cooke's reply on the question to the *Surrey Comet* is a model of the "retort courteous." So admirable, indeed, is this letter from every point of view that, though not directed to ourselves, we reproduce it in another column. Amongst the most telling points in regard to the whole situation which Mr. Cooke brings out are that the average motorist most obviously behave with decency, since, in order to catch him, the police have to set their traps on unfrequented roads, where there is no danger, and not near villages where there is; and that the object aimed at by the police is obviously to collect fines and not to protect the public, as the places where the most danger to the public exists are exactly the spots at which no traps are set.

An Extension of Activity Desirable.

ON the roads which it has taken under its protection, the Automobile Association is unquestionably deserving well of the motoring public, for no more admirable work in connection with the automobile movement can be done than preventing, by means of a carefully devised system, automobilists from unwittingly transgressing the law of the land, particularly when the "blue deep minion of the law" (as Kipling terms him) is hiding in one of his undignified ambushes with a view to catching the unwary. To this the activity of the Association is confined. These unintentional excesses of speed have led to so much ill-feeling, particularly where they have resulted in appearances before the police court, that as the Automobile Association succeeds in stopping them the final elimination of all bad feeling between members of the public and automobilists should be confidently anticipated.

Finances Needed.

"THERE are hills beyond Pentland, and lands beyond Forth." There are other roads besides the Portsmouth and Brighton roads on which similar objectionable tactics are employed by the reapers of fines. There is the celebrated trap in the neighbourhood of Andover, whose victims have to "hand-over" to Col. Harmar, and the other *croupiers* of the Bench, fines on a regular tariff, arranged, apparently, simply on the principle that if they plead guilty they pay £3, and if they defend themselves, £5 and upwards. There is Knaresborough, which has sprung into prominence with a notoriety that almost rivals Andover. And there are others. It is desirable that the same methods should be adopted of preventing unintentional breaches of the law by motorists in these districts also. But for this obviously an extension of the financial resources of the Association will be needed, and to obtain this, increased membership is the natural and proper method. In fact, there seems to be no reason why membership should not be sought for, and the moderate annual subscription paid by practically all the motorists in the United Kingdom. It would amount to one of the cheapest insurances, not merely against the danger of losing money in unjust and unreasonable fines, to which everyone of them is at present liable, but would also be an insurance against the petty persecution and the annoyance of having to attend in police courts and having their licences endorsed.

The Advent of Utopia.

A SCHEME of tremendous magnitude has recently been mooted—not for the first time—in the columns of the daily Press. We refer to the proposals which have been recently put forward for the construction (by means of company promotion, we presume) of a network of special roads designed only for high-speed automobile traffic, and on which only automobiles would be permitted to run. The project, which is at present associated with the name of Sir Douglas Fox, proposes that the roads should bridge the ordinary roads of the country where they cross them, so that no level crossings would be necessary, and no interference with the arrangements of ordinary traffic by the high-speed locomotion be possible, while the high-speed motor roads themselves would be divided down the middle, so that the chances of two vehicles meeting one another end on would be eliminated.

It is an attractive, not to say Utopian, scheme, and, had it not been previously suggested, would certainly lead the public to conclude that Sir Douglas Fox had been dining occasionally with Mr. H. G. Wells. In fact, we shall probably next hear that the new roads are to be paved with Mr. Wells' Eadhamite—one of those discoveries by which the period intervening between the present and Mr. Wells' Utopia is to be rendered famous. In fact, we have our doubts whether the scheme is a practical one. The enormous expenditure on the railways of the country was incurred owing to the possibility of the speculators who found the money being ultimately able to get it back. They, received as an inducement to incur the risk they ran, complete monopoly of the roads they constructed. It is difficult to see how a similar paying monopoly could be created for the very adventurous speculators, if such there be, who embark on the automobile road project. We do not say it is impossible, but we do not see how it is to be done. The moment anything like a considerable fee is charged for the use of the roads by motor cars, all but speed maniacs would continue on the ordinary roads. Of course it would be possible for the road constructors to run automobile services of their own just as the railway companies do trains, and it is just possible that in certain places, and under certain conditions, such a service here and there might be made to pay. But that is not the project. Its commercial aspects, as it actually stands, seem to us at least problematic.

Doubtful Policy.

FROM one point of view we rather regret to find this separate road project being seriously advocated. The Automobile Club, the Motor Union, the Roads Improvement Association, and everyone interested, not merely in the automobile movement, but the future development of the country, are anxious to see both the construction of the roads we at present possess, and their administration, reformed from top to bottom, so as to render them somewhat more suited to modern requirements. Much of the driving force behind this movement will be paralysed if a notion is to gain ground that sooner or later automobilists will have their own roads. In addition, the proposal almost amounts to a recognition that our roads are only designed for horse traffic, and that automobiles are interlopers upon them. It has often been pointed out that our road network, as we have it to-day, is practically the same as it was a hundred years ago. There are but too many reactionaries who wish to see the amount of national traffic restrained by the existing roads rather than as the progress of the country demands that the roads of the nation should be expanded to fit the requirements of growing traffic.

There is another aspect of the situation. Gradually, by more or less drastic methods, the Automobile Club is eliminating the reckless driver, and by so doing improving the general feeling between motorists and other road users. The appearance on the scene of a scheme advocating that motorists are to be provided with roads of their own by private enterprise does not exactly amount, perhaps, to a repudiation of their right to the ordinary high roads, but it would certainly be used by opponents as an argument to show that automobilists are recognising that their vehicles are too dangerous to be allowed to continue permanently in use on ordinary high roads. This would certainly create a very serious situation.

Already Bearing Fruit.

THAT the anti-automobile Press will not be slow to adopt the attitude referred to above, is pretty clearly shown by the appearance of the following observations in a leading morning paper, which has been generally conspicuous for its hostility to the movement:—

MOTOR CAR ROADS.

The suggestion is made that special roads should be built by the public for the convenience of the owners of motor cars! Let the public carefully note what this really means. (1) It is impossible for a motor car to be maintained by a man with an income of less than, say, £750 per annum. (2) There are not more than 250,000 persons in the United Kingdom with incomes of £750 and upwards. (3) The population of the United Kingdom is 43,000,000.

Ergo, the construction of motor car roads would be a special provision out of public funds for the rich.

The Car Ecclesiastical.

A NOTABLE feature of the meeting of the Church Congress this year was the amount of attention bestowed on the topic of automobilism. It was natural enough, of course, after the departure made by the Bishop of Liverpool in adopting a motor car presented to him by some of his admirers, to which we referred last week. Next to the medical profession it is probably the clergy who, as a professional body, find themselves compelled more than any other class of the community to cover considerable distances in all kinds of weather.

"Wide was his parish and houses far asunder,
But he ne left nought for no rain ne thunder."

as Chaucer says of his parish priest. To the parochial clergyman certainly the motor car is coming, if not as a revelation from on high, at any rate, as a means of escaping many a slough of despond and discomfort here below, looming large amongst which may be mentioned the abominable difficulties of getting from one point to another by cross-country railways even where the places are thus connected. At present the opinion seems to be that the ecclesiastical motor car should be the outward and visible sign of the bishop, and perhaps the bishops have greater occasions for its use, but there is no doubt that what is the bishop's to-day will be the country rector's to-morrow, and when every country clergyman has a motor car of his own he will be undoubtedly a happier and a healthier man.

Another Abuse of Executive.

It would seem that a new form of police trap, and one in some respects more objectionable than any that have preceded it, has recently been invented. Instead of the measured furlong (or other distance) with which we are familiar, with a constable (disguised and with a stop-watch) at one end, and a constable in uniform to stop the car at the other, two constables take up their positions at a greater distance apart, say three miles, each with watches which they have previously synchronised as well as they can. The first policeman takes the number of every car passing him, and the second one holds up his hand and stops each car, pointing out to the driver that it is such and such an hour, that he has been timed over the last three miles, and that if his speed is found to have been excessive he will be summoned. We are not yet aware that any cases founded on such evidence as this have been decided, and even Andover or Horsham magistrates might hesitate to convict upon it, for it is so obvious that a little subsequent or previous adjustment of notebooks or stopwatches could make out nearly every car to be an

offender. But the point on which we object and to which the Automobile Club or the Motor Union ought, we think, to take decided action by addressing joint committees, Chief Constables, or otherwise, is that stopping cars unless they are known to have committed an offence, and merely on the chance of their having done so in this manner, is a gross abuse of the executive functions of the police. A policeman has no right whatever to stop a car unless he can charge the driver with having infringed the Act and honestly believes him to have done so. Needless to say, however, the whole business is merely of a piece with other proceedings of the same kind which have elicited not unnaturally the expressions of indignation to which we refer elsewhere. These tactics, however, are so utterly unwarranted by the law that we think Chief Constables would probably order them to be discontinued if approached by the representative bodies we have named.

The Apotheosis of the Horse.

WHEN all has been said, both by his unwise detractors and by his sometimes equally unwise admirers, the horse, at any rate, when well bred, remains a highly intellectual animal. To employ intellect for mere drudgery is to waste the resources of the community, and every really progressive soul will therefore rejoice to hear, on the authority of Mr. Hunting, who delivered the opening address of the annual meeting of the Royal College of Veterinary Surgeons, to which we referred last week, that 20,000 horses have already been displaced by electric trams, and that this process still continues. Mr. Hunting does not think that the motor has as yet made any appreciable inroad upon horse slavery, but on that point we respectfully beg to differ. There are now quite a number of motor 'buses at work in the Metropolis alone, and a further considerable number in the provincial towns and on country routes, while their number is increasing as rapidly as manufacturers can supply the demand. Each horse 'bus that is displaced by a motor 'bus represents the emancipation of from ten to twelve horses. Possibly the horses at present thrown out of work will feel the pinch, but the effect of motor vehicle development can, as we have always insisted, in the long run only mean the setting free of horses in general from the worst of drudgery, and their dedication to the pursuits of hunting, steeplechasing and racing—for which they are pre-eminently suited, and in which they feel a personal interest and enjoyment instead. In fact, as far as the effect of the motor industry upon the horse is concerned, it will ultimately mean a smaller number of very much happier horses, and such a consummation is one for which the real horse-lover will be devoutly thankful.

THE Douglas Corporation have declined to license motor 'buses to ply as stage coaches along the Marine Promenade. The main reason no doubt governing this decision is that the Corporation are the owners of the horse trams along the sea front, the public therefore have to put up with the usual inefficient service resulting from monopoly. This is a good instance of the mistake of corporations running trading ventures of this nature, as not unnaturally the authorities are not very keen to grant permission for a competing service, and thereby render the investment of the ratepayers' money a dubious speculation.

THE 1905 ARGYLL CARS.—PART I.

A VERY special interest now attaches to the Argyll vehicles in view of the enormous scale on which they are in future to be turned out, for it is certain that they will shortly become one of the most familiar—if not the most familiar—of any one make of car on the roads in this country, and that they are destined to be immensely popular with those who require a good, serviceable, and inexpensive British car. Even at the manufacturers' old works in Glasgow, the output has in the past been very large, for, in spite of the difficulties that have necessarily been encountered when constantly extending the equipment of works originally laid down on a comparatively small scale for other work, the old shops at Bridgeton have been rendered remarkably efficient by good management, and have always been kept thoroughly up to date in the way of machine tools. In them, practically every portion of the cars has been turned out from raw materials on the premises, and all improvements in auto-

own works. When it is considered that all the bodies have also been turned out in the Bridgeton factory, it is little short of surprising to learn, after seeing over the old premises, that twenty cars a week were being turned out, as was the case at the time of our visit. It is brought home to one, then, that the demand for Argyll cars must have grown in a phenomenal manner—which could only result from real merits—and, even more forcibly, one is compelled to realise that Mr. Alec Govan—the controlling practical spirit of the concern—possesses extraordinary powers as an organiser.

What will-be Done in the Future.

What has been done in the past, under much less favourable circumstances, renders it possible for one to form some idea as to what will be done in the future. Hitherto, as we have said, the Argyll Company have succeeded in turning out cars which have given great

The 24-h.p. Argyll Landaulette, as an open carriage.

mobile workshop practice have been absorbed as they have come along. During a visit which we paid to these works in the summer, for instance, we could not help being particularly struck by the large percentage of entirely new tools in the machine shop; evidently no out-of-date machinery was allowed to remain there long, and clearly the management understood that only with such an installation for ensuring accuracy of workmanship, as well as interchangeability of parts, could the great advantages of using only the highest grades of materials, and of hardening and grinding all important machined surfaces, be realised to the full.

What has been Done in the Past.

It is true that hitherto it has not been possible for the company to build all the engines which they have fitted to their cars, and that they have employed the well-known Aster make of engine on certain types, but apart from that fact, it is true that all Argyll vehicles have been built from first to last in the firm's

satisfaction to customers, but the demand thus created has exceeded the productive powers at their disposal, with an obvious two-fold result—firstly, that they could no longer benefit to the full from the reputation that had been established, and secondly, that comparatively little advantage could be taken of a largely increased possible output to cheapen the cost, and to improve the processes of production in the way that it might be made to do.

Now, however, all this is being changed, and the necessary steps have been taken for enabling the Argyll cars to be turned out in very large quantities from a huge factory near Glasgow laid out expressly for the purpose, and equipped with the most suitable plant. The new works at Alexandria, which cover 12½ of the 60 acres acquired by the company, are rapidly approaching completion, and a part of them—the 2½ acre machine shop—is already in full swing. They form a remarkable institution, and will be quite *the* show-place for motorists, even in that remarkable engineering district, for they have

been planned out, regardless of prime cost, on the lines of all that is most efficient in the largest and most up-to-date workshops of the world. The company—"Argyll Motors, Limited"—have, in fact, made a bid to be one of the largest builders of petrol cars in existence, and have started out with the full determination of ranking second to none as a purely manufacturing motor car concern.

A Word about the New Works.

Of the new works themselves—which we recently inspected—much, indeed, might be said, but we are chiefly concerned in this article with the cars that are to be turned out rather than with the new factory, and have not, therefore, anything like adequate space to spare. Just as even the name of the place—Alexandria—is at first suggestive of the United States rather than of this country, so many of the most noticeable features of the works are reminiscent of "big things" abroad. The least technical visitor cannot fail to be struck with the imposing frontage with its granite pillars, the marble entrance hall, and the elaborate arrangements that are made for the comfort and convenience of all, any less than is the practical motorist with the "long feeding and receiving" stores with its overhead railway, leading down each bay, the light and airy fire-proof shops with bitumen or wood flooring, and the power-plant with its six gas-producers, indepen-

dent high-speed engines in the different departments, and conveniently arranged shunting and clutches. And, for the engineer, the machine-tools alone are well worth a visit from afar. It is sufficient, however, to say here that the buildings now in course of construction are intended to cope with an output of about forty cars a week, that they only cover a comparatively small portion of the land available, and that—in accordance with well-recognised sound policy—they are designed in such a way as to facilitate systematic extension at any time.

The Advantages of Quantity Manufacture.

Needless to say it is a good, useful type of vehicle that has been developed by the Argyll Company, for otherwise it would have been futile to have taken up the manufacture on so large a scale. Even as it is, it must necessarily be something of a bold undertaking to turn out any particular models in very large numbers in *anticipation* of a corresponding demand, though it is a kind of venture which is most welcome in the best interests of the British industry.

It is only by building cars in quantities that their cost can be kept down, and it is only by making them in advance that immediate delivery can be given to purchasers—a more and more important consideration as time goes on.

Fig. 1.—View, from above, of a typical Argyll Chassis. This illustration, which is reproduced from a photograph of the 24-h.p. chassis, shows the entire mechanism, fixed in place on the frame. It gives, in particular, an excellent idea of the manner in which the hand-operated brakes are "compensated."

Fig. 2.—The 24-h.p. Argyll Chassis, as seen from the “off” side. The special arrangement of the change-speed-lever (L) and the “reversing” lever (N), which operate the “Govan” three-speed gear, is well illustrated in this view. The four-cylinder Argyll engine, the multiple-disc clutch, and the staggered spokes in the road wheels will also be noticed. Attention should however be drawn to the absence of the dust-proof casing beneath the engine, clutch, and gear-box, this having been removed for convenience.

Manufacturing v. Selling.

Although it has been said that the new works near Glasgow will form—and, indeed, already form—a very attractive “show-place” for motorists, and for those who may be interested in motoring, yet it will readily be understood that the parent company—“Argyll Motors”—will be manufacturers pure and simple, and that they will take no direct part in the retail sale of cars. For disposing of their output, they already have agents in all the principal centres, their largest agency being that recently opened in London by Mr. Eustace H. Watson; this large showroom in Newman Street, W., is a worthy counterpart to the new factory, of which we have been speaking above, for it not only enables those residing in the London neighbourhood to select a car without delay from the forty or fifty that are to be at all times in stock, but it will store every component part of each standard model in readiness for immediate delivery on demand.

Characteristic Argyll Features.

The Argyll cars, which are made in several sizes, including those having 4 and 2-cylinder engines, are—speaking quite generally—of the well-known and orthodox live-axle type. They are not, however, mere slavish copies of any particular Con-

tinental model, for they possess a number of special features of their own.

These are, with but few exceptions, incorporated into the design of each size of car, and the more important of them may be briefly enumerated as follows. Probably that which will appeal most forcibly to intending purchasers is the change-speed mechanism, for this is designed in such a way that no sliding spur-wheels are brought into mesh with one another while the car is in motion, and therefore no special skill is required in operating it. It gives three forward speeds and a “reverse,” and it affords a direct-through-drive on the top speed. Next in importance, possibly, is the clutch, for on all but the smallest Argyll cars, multiple disc clutches of the Hele-Shaw pattern are employed, but hardly less noteworthy are several other details which will also be dealt with in an adequate manner in due course.

Merely to draw attention to them now, mention should be made of the pressed steel frame, the side members of which have a Π -shaped section; the tubular front axle, which is strongly stayed on the underside; the “live” rear axle, which not only has roller bearings, but is constructed with a detachable cover-casting forming the upper portion of the casing; the road wheels, which have

View of the 24-h.p. Argyll Landaulette, as a closed carriage.

staggered spokes that give them great lateral strength, and also enable them to be tightened up if the wood should shrink; the steering-gear, which is of an adjustable, worm-and-nut pattern; the centrifugal circulating pump, which has no stuffing-box; the neat hand-levers that are fitted above the steering-wheel; the simple type of rod-mechanism which is employed for connecting the small control-levers with the parts operated by them; and the strong, well-finished bodies, which have pressed-steel panels.

Present Standard Models.

This year's pleasure vehicles include those of 26-30-h.p., 24-h.p., 16-20-h.p., and 12-14-h.p.—all of which have 4-cylinder engines—in addition to a twin-cylinder vehicle of 10-12-h.p. Of these, the 24-h.p. model alone has an Argyll engine, the others having Aster engines. Except in comparatively small details, all are designed on the same general system, such differences as there are—apart from size and strength of each part—referring chiefly to the clutch, the universal joints in the propeller-shaft, the adoption of a thermosiphon system for the cooling water, and to the provision of a magneto as an alternative ignition apparatus. All but the 10-12-h.p. model have, for instance, metal-to-metal multiple-disc clutches, whereas this smallest type of car has an internal leather-faced cone clutch instead. In the same way, a different type of universal joint is used on the largest models to that employed on the less powerful vehicles, and all cars, except the 10-12-h.p. type, have pumps for circulating the water through the cylinder jackets. A high-tension magneto forms a part of the equipment of the 24-h.p. Argyll engine, but magnetos are not always fitted to the other engines.

Attention has also been devoted to the manufacture of light vehicles for commercial purposes, and a 15-cwt. delivery van forms one of the standard Argyll types.

Amendments to the Laws governing Motor Cars.—The following is a list of the principal amendments to the Motor Car Acts which the Joint Committee of the Automobile Club and the Motor Union have formally resolved to recommend to the Royal Commission on Motor Car Traffic:—

(1) *Speed Limits.*—The abolition of all arbitrary or fixed speed limits, on the ground that such limits are not desirable in the interests of public safety, as they tend to weaken the law requiring an automobilist to drive at all times with due regard to the condition and use of the highway, and to the amount of traffic which is or may be reasonably expected to be upon it.

(2) *Driving Licences.*—(a) Licences to be endorsed only for serious offences, viz., those against the provisions of Clause 1 (reckless driving), Clause 5 (forgery, &c., of identification mark or licence), and Clause 6 (not stopping in case of accident), the question of endorsement to be within the discretion of the magistrates.

(b) After a lapse of three years from the date of last endorsement, an automobilist shall be entitled to receive a clean licence.

(c) To add the words "within a reasonable time" after "produced," in Clause 3, Sub-section 4, which now reads, "A licence must be produced by any person driving a motor car when demanded by a police constable."

(3) *Appeals to Quarter Sessions.*—The right of appeal to be given against any conviction for an offence in connection with the ownership or use of a motor car irrespective of the amount of the penalty and the Act under which the proceedings are taken.

(4) *Notice of Prosecution.*—That notice of intended prosecution for any offence in connection with the ownership or use of a motor car be given within seven days of the time the alleged offence was committed, or within seven days of the date on which the identity of the offender was ascertained.

(5) *Fines and Fees.*—All fines and fees imposed and levied under the Motor Car Acts to be paid into the Imperial Exchequer,

The 10-12 h.p. chassis is similar to that employed for the pleasure vehicle of like power, but its construction is modified in certain respects in order to render it specially suitable for its work. It is naturally geared lower, and it has a pump for the cooling water.

Any of the standard pleasure cars can be fitted with bodies of different kinds. For this reason, the 12-14 and 10-12-h.p. chassis are made in three different lengths. The two largest models have 10 ft. and 9 ft. 3 in. wheel-bases, and can thus take any type of body, but the wheelbase of the smaller models is either 7 ft., 8 ft. or 8 ft. 6 in., according as to whether a tonneau, side-entrance or landaulette vehicle is required. The bodies usually fitted include broughams and wagonettes, in addition to those already mentioned, and many very useful and handsome patterns—with and without detachable tops, and with and without canopies and glass fronts—have been designed. All Argyll cars have a distinctive and pleasing appearance, which is largely enhanced by the excellent finish of the carriage-work, and the high quality of the upholstery.

In all cases, the "Govan" type of change-speed-gear is used, three forward speeds and a reverse being rendered available. The gear-ratios naturally vary considerably on different kinds of vehicle, but, roughly speaking, the top "speed" is equivalent to 35 miles per hour on the more powerful cars, and to 26 miles per hour on the smaller models—these rates of travel being based on the normal engine-speed of 1,100 revs. per min. The 2nd speed is always half the 3rd, and the 1st is half the 2nd.

The maker's light delivery van, which has a wheel-base of 9 ft. and is provided with 3-in. solid rubber tyres on the driving-wheels, is usually geared to 4½, 9, and 18 m.p.h. The van body proper has a large capacity for goods, the standard dimensions being 5 ft. 5 in. (length) by 4 ft. 2 in. (width) by 4 ft. 9 in. (height).

and to be devoted to the widening and improvement of highways.

(6) *Appeal to Local Government Board.*—Right of appeal to the Local Government Board to be given in cases in which a local authority refuses to license properly-equipped motor omnibuses or other public service vehicles, or closes bridges to motor cars.

(7) *Examination of Drivers.*—The suggestion for compulsory examination by the officials of public authorities is not one that can be supported, as experience has shown Government examinations for motor car drivers to be useless from the point of view of public safety.

(8) *General Identification Marks.*—General identification marks to be available for use on cars used by makers and agents for general trade purposes, and not to be limited to cars on trial on completion or trial by an intending purchaser.

Motor Volunteer Corps.—Notice is published in the *Gazette* that Capt. W. G. Davis Goff has been retired under the conditions of Paragraph 103 Volunteer Regulations.

A NEW line of motor 'buses was last week started by the London and District Motor Omnibus Company, between Charing Cross and Putney, via Leicester Square, Piccadilly Circus, and Brompton Road. In order to distinguish this company's cars each has prominently displayed on the side panels a large arrow, the service being known as the "Arrow." Other services in the London district will be in similar manner started, each having its distinctive coloured arrow indicating the route.

THE 18-H.P. REGENT CAR.—PART II.

Fig. 4.—The 18-h.p. Regent Car. View from the front showing the front axle and radiator. It will be noticed that the tie rod of the steering gear lies behind the axle instead of in front.

The Engine.

THE engine, which is shown from both sides in Figs. 5 and 6, has its four cylinders cast in pairs, with the valve-chambers arranged symmetrically on either side. The mechanically-operated inlet-valves are placed on the right, the exhaust-valves are on the left. The two cam-shafts are driven from partially-enclosed gear-wheels, which lie in front of the engine; the cam-shafts lie outside the crank-chamber proper, and are secured in place by detachable cover plates, which render them particularly accessible. For each cam-shaft there are two independent cover plates, bolted obliquely to the wall of the crank-chamber, and carrying the guides for the push-rods. Between these two covers there is a short length of exposed cam-shaft. Above each valve is a screw-plug fitting which serves as an inspection cover, while cocks are fitted in the cylinder-heads for conveniently injecting paraffin when necessary.

Mounted alongside the engine, on the inlet-valve side, is the low-tension magneto, D (Fig. 6), which is gear-driven from the cam-shaft spur-wheel. The ignition wire from the magneto passes to a conductor bar mounted alongside the cylinder heads, and electrical connection to the live terminals of the igniters is made by four chopper-switches which, besides serving as neat and efficient contacts, also provide a ready means of quickly testing the ignition. The igniters, which are mounted on iron plates, are bolted to the sides of the inlet-valve chambers, and they are positively operated by the tappet-rods which lie in contact with cams provided for them on the inlet-valve cam-shaft. These cams are exposed, for they lie outside the cover-plates, and this makes it possible to employ a very simple and accessible timing gear, which in this case merely consists of movable rollers interposed between the lower ends of the

tappet-rods and the cams. These rollers are suitably supported in guides, and they are connected by levers to a rock-shaft which is mounted in brackets attached to the crank-chamber casing. The rock shaft is interconnected with one of the levers above the steering-wheel, and is capable of being rocked over so as to alter the position of the rollers relatively to their cams, which causes the tappet-rods to be lifted earlier or later, and, consequently, the ignition to be advanced or retarded accordingly.

The carburettor, which lies on the same side of the engine as the magneto, has the ordinary type of float-feed chamber, which is supplied with petrol by pressure-feed from a tank situated at the back of the frame. The pressure-valve, F, controlling the pressure in the petrol-tank, is situated immediately above the exhaust-pipe and is visible in Fig. 5. No automatically-operated valve is fitted on the carburettor, which draws its supply of warm air through a pipe which terminates in a box surrounding the exhaust-pipe, but the main throttle-valve is interconnected with an auxiliary air-valve, E, which compensates for variations of load. In the warm-air pipe is a sliding port which enables the temperature of the air supply to be

Fig. 7.—The 18-h.p. Regent Car. View of the dashboard showing the neat fittings which are mounted on it. The control levers and pedals are also shown and part of the lubricating tank, G, which lies outside the frame, is also visible.

when an additional supply is deemed necessary.

General Appearance.

The Regent chassis is being placed on the market fitted with a roomy side-entrance body painted and upholstered in Napier-green, and the fittings, which are all nickel finished, give the complete car a particularly smart appearance. The bonnet and the control levers above the wheel are of the Mercedes type, and the fittings on the dash are, as is evident from Fig. 6, particularly well arranged.

Dimensions.

The following are the principal dimensions of the Regent car:—

Engine. — Bore, 90 mm. ; stroke, 120 mm. ; h.p., 18 ; speed, 1,000 r.p.m.

Chassis. — Wheel base, 9 ft. 6 ins. ; track, 4 ft.

Wheels.—Size, 810 mm. × 90 mm.

Complete Car.—Length, 12 ft. 9 in. ; width, 4 ft. 9 ins. ; weight, 19 cwt.

Fig. 5.—The 18-h.p. Regent Car. View of the engine from the near side showing the jacket surrounding the exhaust pipe, from which the carburettor takes its supply of warm air; also the prominent position of the pressure valve, F, for the "pressure feed."

varied. The throttle-valve is under the driver's control in the usual way, being connected to a hand-lever above the steering-wheel. It is also connected to a centrifugal governor, however, which thus automatically controls the speed of the engine, but the effect of the governor is subject to the position of the throttle-lever, which is interconnected with it through a spring.

Cooling is effected by the usual type of centrifugal pump, which is gear-driven from the engine. A honey-comb radiator forms the front of the bonnet and immediately behind this is a belt-driven fan. The lubricating oil tank is situated outside the frame near the off-side front step, and the oil is fed to the lubricator on the dash—from which it finds its way by gravity to the bearings—by means of the exhaust pressure, the same pressure-valve which is used for the petrol supply being used for this purpose also. On each side of the lubricator is a neat glass oil-cup fitted with a plunger for forcing oil directly into either half of the crank-chamber

Fig. 6.—The 18-h.p. Regent Car. View of the engine from the off side, showing the magneto, D, and the chopper-switches, D¹, for the igniters. The carburettor and the auxiliary air valve, E—which is interconnected with the throttle—are also prominent in this view.

A Seasonable Banquet.—While most of the London streets are "up," and the roadway of Piccadilly resembles nothing so much as 203 Metre Hill at Port Arthur after it was taken by the Japanese, the Paviers Company have appropriately selected the occasion for holding their banquet. The chairman of the Company, in reply to the toast of the evening, admitted what few present (or elsewhere) would dispute, that though great advancement had been made in paving the City streets, there was still room for improvement. The chairman hoped that he would live long enough to see the City without a horse, though his reason for anticipating the horseless age in the City appears to have been his rather touching belief in the future of electricity. "Electricity," he said, was in its infancy (we are always hearing this), while horses were on their last legs." As far as the disagree-

able task of pulling vehicles is concerned that may be the truth, but it does not seem at present that it is electricity that is likely to supplant them. At the same time, without sharing his reasons, we may share his hopes that a horseless age for the City is rapidly approaching. The Paviers Company no longer, we are informed, exercises active control over the trade. Let us hope, considering the progressive sentiments uttered, that if it did so, the workers of London streets, when the roads are up, would not be permitted to leave off at mid-day every Saturday and to do no overtime work. However, the united Press of the Metropolis has made fun of this quaint state of affairs for ages, but, apparently, it will continue till the Paviers Company adds another four centuries of existence to those which it has already enjoyed.

THE EMPIRE SPRING WHEEL.

(Continued.)

Action of the Springs.

IN order to illustrate this principle of compensation, we have prepared the diagrams shown in Fig. 2. To a certain extent these diagrams represent the internal arrangements of the "Empire" wheel, but they are not intended in any way to illustrate its construction, for this will be described presently. No reference letters, in the usual sense of the term, have been used on these diagrams, but the outer circle is supposed to represent

Fig. 2.—Diagrams illustrating the compensating system adopted in the "Empire" wheels, and showing how the distribution of the load, W , is affected by the number of points of support, R .

the rim, and the inner, star-shaped member represents a casting which is mounted on the axle and carries the leaf-springs, one of which will be seen between each pair of radial arms. The springs rest on rock-levers, and their centres are anchored by bolts to the star-shaped casting. In the left-hand view, the axle is supported at one point only, while, in the right-hand view, there are two points of support. The load due to the weight on the axle is denoted by the letter W , while the reaction or virtual upward lift of the ground is denoted by the letter, R . In

the left-hand diagram, R is concentrated at one point; the spring which rests on R is stressed, therefore to the maximum. By virtue of the rock-levers which support the ends of each spring, however, all the springs are similarly stressed. It is these rock-levers which form the essential element in the compensating device, and the distribution of the forces due to their presence is denoted by the reference letters W . In the right-hand diagram the reaction, R , is distributed over two points of support, each of which lifts upward with a force equal to $\frac{R}{2}$, and the springs resting on them are therefore only

stressed to $\frac{W}{2}$, or half their maximum. All the values assigned to the distributing forces in the right-hand diagram are exactly half those in the left-hand diagram. The load on the springs, therefore, in such a wheel as is here diagrammatically illustrated, would fluctuate from $\frac{W}{4}$ to $\frac{W}{2}$ five times in every revolution, or 3,300 times in a mile with a 32-inch wheel. At 30 miles an hour this means 1,650 fluctuations per minute. If the springs were not compensated, the periodicity of the fluctuations would be reduced by four-fifths (i.e., to 330 per minute), but the deflection of each spring would be doubled.

By altering the number of points of support, so that they vary between three and four, instead of between one and two, the fluctuation of stress is then from $\frac{W}{3}$ to $\frac{W}{4}$, that is to say, it has been reduced by five-twelfths—the importance of many points of support is, therefore, obvious. The foregoing remarks apply solely to the running of a wheel over a perfectly smooth road. This is naturally only one part of the work which any spring wheel is called upon to perform, but in other respects the "Empire" wheel acts as a shock-absorbing

Fig. 3.—The "Empire" Wheel. View of the interior after removing the cover.

Fig. 4.—The "Empire" Wheel. Elevation showing general arrangement of parts.

device in much the same way as with those of other inventors. From the shock-absorbing point of view the "Empire" wheel has a "full" range of action, by which we mean that slight road unevennesses of any kind have an effect upon the springs.

Construction of the Wheel.

Several types of wheel have already been designed by Mr. Robinson to suit the different kinds of work which it is intended that the "Empire" wheel should undertake. All these types, however, virtually belong to either one of two standard patterns, both of which we are now able to illustrate and describe. There is a considerable difference between these two models, in fact, in a sense, one of these may be said to be the inverse of the other. The first model which we will describe is that illustrated in Figs. 1, 3, 4, 5, 6 and 7; it is a wheel designed for use on touring cars, and an experimental set has been in use on a car for many months. In Fig. 3 the outer cover of the wheel has been removed in order to show the interior, of which Fig. 4 is a drawing. In Fig. 6 a smaller portion of the interior is shown on a larger scale in order to better illustrate the construction, and Fig. 7 is a photograph of the wheel after removing the resilient member, and this illustrates one of the most important features of any spring wheel, viz., the method of aligning the wheel on the axle and supporting it under the side shocks to which any wheel is perpetually subjected.

Referring to Figs. 4 and 5, the axle, A, is fitted with a perforated sleeve, A², which forms an oil box for the proper lubrication of the hub member, B, which is retained in place by the nut, A¹, in the usual way. The hub member, B, is much the usual type of "housing" to that employed in artillery wheels, it has a fixed flange, B¹, and a corresponding loose flange opposite to it for securing, by the bolts, B², what would in the ordinary wheel be the spokes. Instead of spokes, however, there is in the "Empire" wheel a star-shaped casting, B³, which has, in the wheel illustrated, five radial arms. Each of these arms terminates in a wide boss, B³, which

forms a pivot for the compensating rockers, F. It is these rockers, F, which support the ends of the laminated leaf-springs, E, and the saddle ends, F¹, of these rockers are, it will be noticed, specially curved for the purpose of giving a true rolling motion between the two surfaces in contact when the wheel is in action.

The springs, E, are anchored to the central casting, B², by hinged bolts in such a manner that they are quite free to take up any oblique position which may be necessary. The springs are held in the clamps, E¹, and these clamps are connected to eye-bolts, E², which, after passing through the bosses, B³, are secured to the casting, B², by the nuts, E⁴. The clamps, E¹, for the springs, are best shown in Fig. 5, but the anchor bolts, E², and the position of the bosses, B³, are very clearly shown in Fig. 6. It will be noticed that the nuts, E⁴, have plenty of clearance to allow for the deflection of the springs, E, and the consequent receding of their anchor bolts under working conditions. Another point to be noticed is that by adding a liner or thickening piece to the saddles, F¹, and tightening up the nuts, E¹, the springs can be initially compressed and might even, if it were thought advisable, be "screwed up" to take all the normal "dead-load" without deflecting. Surrounding the anchor bolts, E², are short helical springs, E³, but these are merely provided as a precaution against damage through a possible breakage, and they are not in any way supplementary springs as the term is generally understood with reference to spring wheels, in fact they are, as will be seen in Fig. 5, normally quite out of action. Before passing on to the other essential details of the wheel it will be as well to draw attention to the fact that the essential features of the compensated system of springs have now been described, and it will, therefore, be easy to understand, in the light of our preliminary remarks, and from what has now been said of the construction, how a load applied to the centre of any one spring is immediately transmitted through the rockers, F, to every other spring in the wheel.

(To be concluded.)

The Retort Courteous.—The following is a letter to which we refer editorially, elsewhere, which has been written by Mr. Stenson Cooke, the Secretary of the Automobile Association, to the *Surrey Comet*, in reply to certain editorial strictures in that journal:—

I am sure the article in your issue of September 20th is influenced by a misconception of the whole matter. Anyone with a knowledge of motoring, however small, will admit that it is quite impossible for the driver of a motor car to estimate its speed within a mile or so per hour. Our cyclist's efforts are therefore directed to the preservation of law and order by warning motorists who are apparently, and in many instances unconsciously, exceeding the legal limit.

Your article infers that the sole duty of the local police is to encourage the commission of offences against the law, and it objects to any organisation such as ours, which by preventing these offences contributes to the peace instead of disturbing it. The law of speed limits has been clearly shown to be both impracticable and inequitable. Instead of having effected any material increase in the welfare of the great general public, for whom all laws are or should be made, the enforcement of this law is abused to an extent which has become unbearable. The motorist is considered not so much from the point of view of the wrongdoer, as a source of revenue. The police leave the towns and villages unprotected while they time motorists on inviting stretches of road, most of which are safe from all possibility of accident. Two conclusions can reasonably be drawn from this.

First, that the average motorist is evidently a gentleman who instinctively considers the well-being of his fellow-man, for the simple reason he does not go fast where there is danger to man or beast.

Secondly, that the primary object for which the police are employed, namely, the safety of the public, is forgotten in the rush for the motor man's money. The question is not one of "safety" but "fines," and this is contrary to all principles of equity for which the law of England has hitherto been justly famed. I can adduce evidence from gentlemen of unquestionable integrity to the effect that in four out of five instances it is not safe for them to drive a motor car through a trap at a higher rate than ten miles an hour without being accused, and in default of overwhelming evidence convicted, of going at more than twice that speed.

Fostered, as it is, by the farmer with horses to sell, by the borough councils with large floating debts which they seem to think motorists should pay, by a Bench who consider that the purchase of a motor car automatically converts an otherwise harmless gentleman into a creature of blood lust to slay all before him, the prejudice is so strong, so rabid, that many a car owner, sick and disgusted with the tissue of erroneous calculations which confronts him, pays his fine rather than go to the further expense of employing counsel to defend his case, whose costs he has to pay even if he is exonerated completely.

Small wonder that the Automobile Association has been formed, not, as I have plainly shown, with the object of thwarting the police, but to relieve them of disagreeable and unnecessary work.

One may doubt if the great men who draft the laws of our country ever expected that one of these laws would be prostituted in a way so loathsome to any clean-minded sportsman, as the setting of traps undoubtedly is, and if our action be deemed ungentlemanly, the conduct of Englishmen who, a hundred years ago risked their lives to save French aristocrats from what a maddened rabble termed justice, was also questionable.

THE CARON MAGNETIC IGNITER.

THE splendid performance of the Vinot car in the Tourist Trophy adds interest to any special feature of its construction, and we, therefore, take this opportunity of giving our readers a description of the Caron magnetic igniter, with which the four cylinders of the Vinot engine were fitted at the time of the race.

Magnetic igniters are self-contained devices for utilising direct the low-tension current from a magneto, both for producing the requisite low-tension spark in the cylinders and for separating the contact points of the igniter. As the name implies, the separation of the contacts is per-

Fig. 1.—The Caron Magnetic Igniter. View showing the comparative size of the Caron Igniter and an ordinary high-tension ignition-plug. The "Burlington" ignition-plug is shown on the left and the Caron Igniter is beside it. On the right is another view of the igniter in which the coil and the plug-fitting with its tubular core are shown separately.

formed magnetically—by utilising the current from the magneto—instead of by push-rods and rock-shafts operated mechanically from the engine as in ordinary low-tension ignition systems, and the inherent advantage of the magnetic igniter is the consequent abolition of these otherwise essential working parts.

Although by no means an innovation in automobile construction, it is only recently that there has been any signs of renewed activity towards the perfection of a detail which in the past has given comparatively little satisfaction for the labour spent upon it. Foremost among the causes which were effective in committing this type of ignition device to comparative oblivion were the high consumption of current (then necessarily supplied from batteries), the difficulty of maintaining compression, and the amount of metal which it was usually found necessary (for constructive purposes) to have projecting into the combustion chamber, but was a source of pre-ignition. The comparative simplicity and reliability of ordinary high-tension ignition systems, using jump-plugs, offered greater attractions at a time when there were so many other more important details in motor-cars to be perfected, and the magnetic igniters were passed over in consequence. In one or two instances, lately, this type of apparatus has come to the fore again, and its good behaviour on trial is drawing increasing

attention to its advantages, which, under the influence of improved magnetos and skilled workmanship, no longer suffer to anything like the same extent from the drawbacks which were detrimental in the past.

Of the various forms in which this type of apparatus is made, the Caron—as fitted to the Vinot cars—is one of the most simple and compact which we have seen. In size it is actually not much larger than an ordinary ignition plug, while as our illustration shows it is almost exactly the same size as the "Burlington" plug, which is of unusually substantial construction. The igniter consists of three principle parts: a coil of wire, A, with an iron core, B, a plunger, C, forming one part of the contact breaker, and a plug fitting, F, for attaching the apparatus to the cylinder in the usual way. The arrangement of these essential parts is best shown by Fig. 2 which is a sectional drawing. The coil, A, does not call for any special mention, but it is compactly wound and neatly protected from accidental damage by a tubular metal sheath. It is also easily detachable from the core as is evident from Fig. 1. The core is made of two metals, the upper part, B, being iron, the lower part, B', being brass. The reason for this is that when the current flows through the coil, only the iron part of the core becomes magnetised; this part is thus enabled to exercise a very direct attraction on the iron plunger, C, which is normally held down lightly against the "earthed" contact, D, by a weak spring, C.

Fig. 2.—The Caron Magnetic Igniter. Sectional elevation showing the construction of the apparatus. The plunger, C, and its helical spring, C', are clearly shown in this drawing.

The external electrical connections for the igniter are similar to those of an ordinary jump-plug, for a separate wire is merely led from the distributing commutator to the terminal on the top of each coil. The action of the magnetic igniter is as follows:—Directly the current is switched on by the commutator it flows through the coil A, and back to "earth" through the contact at D. Simultaneously with the passage of the current through the coil, however, the core, B, becomes a powerful magnet, and it draws the plunger, C, sharply towards it, thus separating the contacts and producing a spark.

For use in conjunction with these igniters, the manufacturers supply a four-pole magneto, self-contained, with its own distributor. The magneto armature is normally short-circuited, but as the distributor arm makes contact, this short circuit is automatically broken, and the current is switched on to the igniter, which operates in the manner already explained.

AUTOMOBILISM has been accused of interfering with quite a number of trades, but for magnificent absurdity commend us to Mr. Jamrack who, through a morning contemporary, informs us that motor cars are causing owners of country houses to give up keeping pet wolves, as they have taken to motoring instead. Perhaps it is as just as well—not to say better.

THE BRITISH ARMY AND MECHANICAL TRANSPORT.— PART II. *(Continued from page 1229.)*

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—The camp at Hurley—looking down the lines. On the right is the first section of the repair train, on the left are the carpenters' shop and foundry which have been unpacked from the second section.

Systems of Transport.

EVERYONE who has ever given a thought to the question of military transport must have realised the enormous difficulties which interfere with mobility and the wide scope of, and in fact the imperative necessity for, mechanical aid. The problem before the designer of suitable machinery for army transport is far more complex than that which faces the constructor of commercial motor-vehicles. The commercial vehicle keeps always to the highways of the district in which it is employed, the military transport wagon, however, has to be capable of leaving the roads and negotiating any country which it may meet—country which may not only be conspicuous for the sheer absence of roads, but for the utter unsuitability of its soil to withstand the heavy strains imposed upon it by the wagons and engines. It is certainly this difficulty of unsuitable ground which forms the fundamental difficulty of military transport, and its primary impor-

tance lies in its being the one factor incapable of modification in practice. Its solution may be considered as a problem by itself, independent—so far as it is affected in general principles—of future developments of mechanical details; although such mechanical improvements are more than likely to be a most important factor in determining the future lines on which military transport will be carried out, should more than one satisfactory scheme be found for overcoming the fundamental difficulties.

At the present time no unusual features characterise the simple transport scheme of the British Army. Standard types of military wagons are dragged one behind the other, in the form of a train, by a standard type of steam traction engine. The steam traction engine is, perhaps, a heavy cumbersome machine, but under the existing system of simple traction its very weight forms a vital part of its constitution. To drag a loaded wagon over the ground it is obviously

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—The Repair Train Smithy. A Milnes-Daimler lorry is seen in the foreground on the right.

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—The Repair Train Foundry. Two men are working on the moulds, and in front is an electrically-driven and oil-fired blast-furnace capable of running 56 lbs. of cast-iron in the two crucibles. Some castings turned out by this plant are lying on the ground.

essential that the engine which draws it should itself be able to obtain a fair purchase on the ground with its wheels. Under ordinary conditions this hold is obtained merely by the friction of the surface of the wheel in contact with the surface of the ground, which is all that prevents the wheel slipping.

The tendency for the wheel to slip is obviously proportional to the power necessarily exerted by the engine to move itself and the loaded wagons behind it, while the friction tending to stop the wheels slipping is merely proportional to the weight which those wheels support. If then they do slip, there are but two alternatives by which they may once more be made to take a natural hold on the ground; one is to reduce the load of the wagons, the other is to increase the weight of the engine. Neither method can be considered as satisfactory, for both reduce the effective value of the engine as a transport machine. The limit, beyond which the engine cannot usefully be increased in weight for field work, is found to be a maximum of 4 cwt. per 1 inch width of tyre, with a 6-ft. wheel. The wheels cannot, of course, be made indefinitely large, so there is necessarily a limit—even if it is not very narrowly defined—to the useful size of engine, and as it is also found in practice that the useful load behind the tractor should not, for field work in unknown country, exceed the weight of the engine itself, there is, therefore, a limit to the size of a transport train as a whole when working under these conditions.

Obviously, therefore, there is room for improvement, and Major Donohue, who has naturally given this side of the subject his very close attention, hopes that before long some really useful development will take place along either one of two lines open to the inventor. The first of these is to improve the adhesive power of wheels without increasing their destructive power on the road, and the second is to utilise the useful load which the engine is dragging, as "adhesive load" for driving

purposes. In connection with improvements on the ordinary wheel, the work of Mr. Diplock—whose "Pedrail" has been so fully described in these columns—is quite unique, and his invention stands alone to-day as the one bold attempt at the practical solution of this particular problem.

On the other side there is Colonel Renard—of the French Army—who has developed and put into actual use a scheme by which the useful load is made effective for the purpose of traction. Colonel Renard's train is already known to our readers; his idea is merely to make one axle of each wagon a "driving axle," and to couple up the engine to each of them by means of a series of universally-jointed propeller-shafts. Under such conditions the weight of the tractor is comparatively immaterial, because its capability of transporting useful loads, hitched on behind, no longer depends on the adhesive power of its own wheels. So far as the load carrying units are concerned, they are no more likely to suffer from insufficient adhesion than is the ordinary motor car, for almost any vehicle can be relied upon to propel itself—given the requisite power—and it is only when it is called upon to drag other vehicles behind it, whose load is independently supported, that these troubles begin to arise. The case is, of course, analogous to that of the railway locomotive and its train, most heavy goods engines having their wheels coupled together to form driving wheels, so that the whole weight of the engine may be rendered effective for the purposes of adhesion, instead of only that portion of it which is supported by the axle which forms the crank-shaft.

Each scheme has, no doubt, advantages and disadvantages peculiar to itself, but at the present day judgment must be withheld until further knowledge, as the outcome of practical experiment, is available.

(To be concluded.)

THE Automobile Club continues to add regularly to their list of members many of the most prominent men in the United Kingdom. In a long roll recently elected

we notice Major-Gen. Sir Edward Hutton, K.C.B., Col. Sir S. M. Lockhart, Sir Hugh Bell, Lord Lucas, and Mr. Edward C. Grenfell.

THE TOURIST TROPHY RACE QUESTION.

So much greater, and so much more general, is the interest that is now taken in the Tourist Trophy type of race—the first contest of the kind having proved so pre-eminently successful—that many of our readers may find it useful to have their attention drawn to the numerous special articles, dealing with this important subject, that have appeared in our pages. The following summary will be found to constitute a handy index to the nature of these previous articles, the continuation of which we resume this week below:—

Engine Tests in the Shop.

Both in the case of the Wolseley engine (slow speed) and of the De Dion engine (high speed), the tests were made to ascertain the rate of fuel consumption at various speeds. First of all, they were taken with the throttle-valve full open and afterwards the throttle-valve was approximately half closed and a similar series of results obtained. Throughout both sets of trials, the time of ignition was varied correctly to suit the speed and suit the load, so that correctness of "timing"—obviously a vastly important item—may be assumed throughout. For the Wolseley tests—for which we are indebted to that company—a dynamometer brake was used for imposing the load and for ascertaining the "pull" and the horse-power. In the case of the De Dion—which we tested

ourselves—the engine was coupled up direct to a dynamo and the power measured electrically. For convenience of reference, the results are shown diagrammatically in Figs. 1, 2, and 7 for the typical slow-speed engine, and in Figs. 3, 4, and 8 for the typical high-speed engine.

Another test made with the Wolseley engine shows how the fuel consumption varies with the horse-power when the engine is running at normal speed, *i.e.*, it indicates the effect of the throttle-valve (variations of load) on economy, and proves the merit of working at full-load when possible. These results are reproduced in graphic form in Fig. 5.

In Fig. 6, the results obtained from tests made with a 3-cylinder Brooke engine are given, and these show the

Fig. 1.—Slow-Speed Engine. Curves showing the "horse-power" and the "pull" at various speeds, both with the throttle-valve full open, and also with it "half" closed.

Fig. 2.—Slow-Speed Engine. Curves showing the fuel economy at various speeds, both with the throttle-valve full open, and also with it "half" closed.

Fig. 3.—High-Speed Engine. Curves showing the "horse-power" and the "pull" at various speeds, both with the throttle-valve full open, and also with it "half" closed.

effect of speed, and of throttling, on the suction of an engine, and therefore on the quantity of mixture which can be drawn into the cylinders. The engine, which had $3\frac{1}{2}$ in. by $4\frac{1}{2}$ in. cylinders, was for this purpose driven by another engine at various speeds (ranging from 200 to 1,000 r.p.m.) and various sized throttle orifices were introduced into the induction pipe—the size of the hole varying from $1\frac{1}{4}$ sq. in. to $\frac{1}{16}$ sq. in. area. A special apparatus was fitted to the induction-pipe—introduced between the throttle-valve and the engine—to indicate the suction in ounces per sq. in. In Fig. 6, the areas of the orifice in square inches are denoted.

The Wolseley Engine.

The all-important facts shown by the tests of the Wolseley engine are (1) that the maximum power (h.p.) is developed at a speed of about 950 revs. per min. with a full open throttle, and that, when the throttle-valve is "half" closed, the highest power is available at about 780 revs.; (2) that the maximum pull (foot-pounds) is obtained at about 800 revs. (the "normal") in the former case, and at 350 revs. in the latter; (3) that the maximum efficiency in relationship to "pull" is got at normal speed when the throttle is wide open, and that—although lower in degree—the best efficiency with a "half" closed throttle is at about 550 revs. per min.; and (4) that the efficiency falls off with ever-increasing rapidity when the speed is allowed to considerably exceed the normal. It should be borne in mind, however, that the carburettor may be very largely responsible for the shape and character of these curves, and that, throughout all the tests referred to in this article, the figures might have undergone considerable modification if a different type of carburettor had been employed instead. But, in spite of this, the curves are probably fairly charac-

Fig. 5.—Slow-Speed Engine. Curves showing the effect, on fuel consumption, of closing the throttle-valve to reduce engine power.

Fig. 4.—High-Speed Engine. Curves showing the fuel economy at various speeds, both with the throttle-valve full open and also with it "half" closed.

teristic of most modern petrol engines, and are, therefore, useful for the purpose of drawing practical conclusions of the kind now needed.

The corresponding morals to be deduced from the four facts enumerated above may briefly be expressed as follows:—(1) The best apparent performance of a car can be secured by letting the engine run faster than its "normal" speed. (2) When hill-climbing on any particular gear, the greatest pull is obtained at normal engine speed; if one is, however, working with a partly closed throttle, the best pull will be got at a somewhat lower speed. (3) It would not pay a competitor in the Tourist Trophy race to allow his engine to materially exceed its normal speed, and if the throttle-valve has to be partly closed, the engine speed should be lower still. (4) Even leaving out of consideration the extra pull that is required to overcome the greater wind-resistance, the fuel consumption of a car is enormously increased if the engine is allowed to "race."

Turning to Fig. 5, one sees the extent to which throttling is detrimental to economy, for although the petrol consumption per hour increases as the horse-power is increased (by opening up the throttle), yet the petrol used per h.p. goes down. It naturally goes down very rapidly at first, less so towards full load.

The further curves grouped together in Fig. 7 are given for the benefit of those who wish to see the effect of speed and load on fuel consumption per explosion, b.h.p. hour, per foot-pound per hour, and per hour only. We do not propose to refer in detail to them.

Fig. 6.—Curves showing the effect of speed and throttle on the suction in the cylinders of an engine. The throttle openings are expressed as areas in square inches and not as diameters.

Figs. 7 and 8.—Curves showing the fuel consumption of petrol engines at various speeds, both with the throttle-valve full open and with it partly closed.

Slow Speed Engine.

This engine and its combined throttle-valve and carburetor were identical with those fitted to the car tested by us.

The De Dion Engine.

Various causes render the figures which we obtained from the De Dion engine less conclusively characteristic of typical engines in general, or even of this well-known make, for not only was the electrical efficiency of the dynamo an unknown quantity, but the engine at our disposal was one that had been in regular hard work for a considerable time, and might well not have been at its best. The speeds, however, were accurately obtained by a reliable tachometer, and the petrol consumption was correctly taken and checked, so that our curves give a good general idea concerning the data required.

In Fig. 3 (which corresponds with Fig. 1 of the slow-speed motor), it is seen that the highest power (h.p.) is obtained at a considerably greater speed than is the maximum pull (foot pounds), and that the effect of throttling is of much the same nature as in the case of the Wolseley tests. The highest horse-power is got at a speed of 1,250 revs. per min., and, with the throttle partly closed (to give half power at about 1,500 revs.), the best power is available at 1,150 revs. The "pull," however, continues to increase with lower engine speeds, so that the tendency, when hill climbing, is for a car to continue running longer without changing gear, even though the engine-speed may have been reduced considerably below the normal by the steepness of the gradient.

Even more important is the fact brought out by Figs. 4 and 8 (corresponding to Figs. 2 and 7) that the fuel economy goes steadily down as the speed goes up, even to the normal, and that the engine becomes seriously inefficient at extremely high speeds. One great difference shown to exist between the two engines by Figs. 7 and 8 should be noted. The fuel consumed per hour steadily increases with the speed in the slow-speed engine, but it rapidly rises and then falls, even more rapidly, in the high-speed engine. This is a point to which reference was made when dealing with the tests carried out on the 6-h.p. De Dion vehicle.

From some points of view, the curves obtained from this high-speed engine appear to form actual continua-

High Speed Engine.

tions of those denoting the characteristics of the low-speed engine, and therefore a very fair idea can be obtained as to what results might be expected from engines that have run at medium normal speeds.

Tourist Trophy Aspects of our Tests.

The main morals to be drawn from the experiments conducted by us have, for the most part, been now pointed out, and it has been very fully proved that economy results from full load (keeping the throttle full open as much as possible), from never letting the engine run faster than its normal speed (not driving "all out"), and—consequently—from having as many different "speeds" in the gear-box as possible. There are one or two equally important points to which attention should be drawn, even if they are obvious to the majority of our readers, these referring to "ignition timing" and to "windage."

Every motorist knows that even when the throttle-valve is left wide open, and the engine is doing no work, the speed of an engine can be controlled entirely by retarding the ignition. It is also clear that the amount of petrol then being consumed is the same as though the engine were developing its full power at that speed, and that therefore an enormous waste of fuel can result from incorrect "timing." The same remark of course applies to pre-ignition, and in both cases—be it noted—injury is apt to result to the mechanism.

The chief point about "windage" is that—unlike road resistance—the extra work that has to be done by the engine, in forcing the car through the air, increases enormously with speed. On a level road, for instance, a car weighing about a ton and having a cross-section of, say, 12 square feet, will require a pull of about 60 lbs. to overcome road-resistance, whatever speed it may make, but whereas the extra pull required to overcome windage (on a still day) may be only 6 lbs. at 10 miles an hour, it is about 54 lbs. at 30 m.p.h., and 150 lbs. at 50 m.p.h. It is, therefore, almost negligible when the car is travelling slowly, but is so serious at extremely high speeds that an additional restraint is automatically imposed on excessive speed by the T.T. rules.

(To be continued.)

RACES, RECORDS, AND TRIALS.

DOURDAN SPEED TRIALS.—Clifford Earp who, with his six-cylinder Napier, made the best time of the meeting, both for the standing mile and the flying kilometre, takes his ease whilst waiting his turn to race.

Dourdan Speed Trials.—On Sunday the speed trials over the kilometre and mile were successfully carried through on the Dourdan measured stretch, under the auspices of the *Journal de L'Automobile*, under the rules of the A.C. de France. Two world's records only were lowered, these falling to Cissac in the motor bicycles under 50 kilogs. class, his time over the standing mile on a Peugeot machine being 53½ secs., beating Giuppone's previous record of 55½ secs. The other new record was also made on a Peugeot motor cycle by Giuppone, his time for the standing mile being 57 secs., beating his own previous record of 1m. 3s.

Clifford Earp, on the 6-cylinder Napier, again upheld Great Britain's position by making the best speed of the whole meeting, his time over the standing mile being 53½ secs., and over the flying kilometre 25½ secs. In the Tourist class, Bablot on a Berliet car, made the fastest time of 1m. 12s. for the standing mile, and 35½ secs. for the flying kilometre. The chief times at the meeting were as follows:—

Racers.

Heavy Cars (1,000 kilogs.).

	Standing Mile.		Flying Kilom.

and Italy, and the number of possible starters amounts to 20. In regard to the American Eliminating Race, the above summary of the times achieved by the cars for the various laps should prove of interest by way of comparison with the times which will be achieved during the race itself to-day. The cars selected to represent America in the race are denoted by an asterisk. The rejection of three of the competitors who succeeded in completing the full number of circuits, and the substitution in their place of three cars which failed to get through, has created an enormous amount of feeling in the United States. During some preliminary trial runs over the course, Walter White, on his White steam racer, has been credited with covering 10 miles in 9 minutes dead, over the winding Jericho Turnpike.

Vanderbilt Cup, 1906.—A formal decision has been come to by the A.C. de France not to participate in this race next year, whatever may be the issue this year. A letter has already been sent to the A.C. of America notifying this decision.

Yorkshire Fells Hill-Climb.—Under the auspices of the N.E. Lancashire A.C., a hill-climbing event was held on Saturday last on the road between Clitheroe and Salford. The course was nearly 1 mile in length. Twenty-five cars took part. Mr. Cayley offered a silver cup for Class C, and medals were awarded in all classes as follows: Class A: Single-cylinder cars not exceeding £200, Dr. V. J. Fox, Belsize car, 3m. 23.5s. Class B: Cars not exceeding £350, A. Huntley Walker, Darracq, 3m. 10.5s. Double-cylinder cars up to £350, E. A. Riley, Belsize, 2m. 46.5s. Class C: Cars up to £500, A. H. Walker, Darracq, 1m. 58s.; Class D: Cars up to £750, George Burton, Daimler, 1m. 42.5s. Class E: Cars up to £1,000, J. R. Thompson, Mercedes, 1m. 47s. Class F: Cars exceeding £1,000, A. Birtwistle, Daimler, 1m. 6.5s.

1906 Trials.—Tyre and lamp trials are to be held by the A.C.G.B.I. next year, probably in February. The postponed Van Trials may be held during the second week of August.

Brighton to Edinburgh.—The run of the 6-cylinder Napier car from Brighton to Edinburgh, during which the top speed only was to be used throughout, commenced on Wednesday morning of this week, under the

observation of the A.C.G.B.I. The car was driven by Mr. Cecil Edge, and a considerable amount of interest anticipated in the car's performance *en route*, as, as far as possible, a specified time-table was adhered to throughout, computed at the rate of just under twenty miles per hour. The following is the time-table for arrivals, after leaving Brighton at 6 a.m., which was issued in respect to this run:—

London, 8.36 a.m.; Biggleswade, 11.51 a.m.; Stamford, 2.6 p.m.; Newark, 4.51 p.m.; Doncaster, 6.45 p.m.; Darlington, 9.54 a.m.; Alnwick, 2.12 p.m.; Dunbar, 6.12 p.m.; Edinburgh, 7.33 p.m.

The gear ratio between the engine and the back axle on the top speed is approximately 4.6 to 1; the tyres are 850 mm. in diameter, so that the speed of the car would be about 38.4 m.p.h., with the engine running at 1,760 revs. per min. We understand that on trial the car attained a speed of 46 m.p.h., in which case the engine speed must have been about 2,100 revs. per min., the car was also made to travel at 5.32 m.p.h., and the engine could then only have been turning at about 240 revs. per min. These figures in themselves are a striking tribute to the extraordinary flexibility of the 6-cylinder engine as regards speed, and now the road trial should show how far such flexibility eliminates the necessity to change speed when touring.

It has been decided by the A.C. de France to carefully consider the possibilities for 1906 of a contest for pneumatic tyres. In this, entries will be confined to makers of motor tyres, and the distance proposed is 1,000 kiloms., spread over two days. Naturally many difficulties stand in the way of satisfactory rules being arranged, especially in view of the very short distance over which it is proposed the test should take place, but it is hoped that in some way the French Club will get beyond the mere *study* of the question and actually institute the competition. In like manner the club have determined to consider the question of an extended tourist car competition through France over a distance roughly of 5,000 kilometres. The proposals put forward by the Marquis De Dion are to form the basis of the governing factors for the consideration for this event.

PROPOSALS are being made to the French A.C. by the German A.C. for the calling of an International Commission to decide upon speed events for 1906. It is suggested that only one big race should be held, all others to be rigorously boycotted. Failing the French club calling the conference, the German club propose calling one to be held in Berlin in November.

MOTOR CYCLING.

Anti-Side-Slip Trials of the C.T.C.—The awards and official report on the trials conducted by the C.T.C., at Cadogan Garage on Whit Tuesday this year—an account of which appeared in our columns at the time—has now been issued. As the tests are of much interest in regard to motor cycles, we give a *resumé* of

pushed through the cover from the inside, and secured in place by nuts on the outside. The report draws attention to two obvious defects, viz., the detrimental effect of the stud heads on the tube, and the liability of damp finding access to the fabric.

Most curious of all is the spring tyre of Mr. W. H. Robson which secured fourth prize. The spiral springs are detachable and are fixed to the special rim by wedges. It is, says the report, a splendid non-slipper and is, of course, unpuncturable. Its chief defect is the noise the springs make upon all roads, but particularly upon stone sets. The springs themselves showed very little sign of wear at the conclusion of the four days' official trial upon the roads selected, but on further testing upon rougher roads, a great many of the springs gave way, and those that remained showed considerable damage. The judges were at first disposed to be sceptical of the value of this device, but in practical use they found it to be more resilient than many of the pneumatic-shod wheels to which anti-side-slipping appliances had been fitted, and, had the springs withstood hard usage upon the road, this exhibit might have taken a higher place. It is the best non-slipper tried, and no grease, mud, or dust was met with that it failed to negotiate; it is at its best on very uneven surfaces, and at its worst on well-laid stone sets. It is, however, decidedly slower than a pneumatic, and the "dragging" is very perceptible, especially uphill. A full description of this "Syrinx" wheel is given on p. 1275.

Four other machines were selected from the preliminary trials as worthy of further experiment. These were Nos. 7, 13, 19 and 30, of which the two latter are represented in our illustrations. Mr. G. S. Sayner's device (No. 7) consisted of a linked chain laid longitudinally upon the tread, and held in place by inflating the air tube. It, however, slipped off the tyre at the preliminary trials, and before the first ten miles had been covered on the road it broke. Tried again the day following, it behaved no better, and, as it seemed to the judges that it would be unsafe to require the competitor to ride it further, it was withdrawn. No. 13, submitted by Mr. W. E. Beasley, consisted of a series of spring steel clips, from which a stud projected on each side of the tread at what was considered to be the most effective angle. Eight such clips were placed on each tyre. These stood the preliminary test on the concrete very well, but after three miles of sets half the bands were broken, and the exhibit was withdrawn. No. 19, submitted by Mr. J. Kirkland, took the form of a number of fine steel wires passing outward through the tread. The points of the wires answered their purpose on the soapy concrete, but after 200 miles on the road they had worn down level with the tread, and their non-slipping properties had vanished. No. 30, submitted by Messrs. Boote and Armstrong, consisted of a series of chrome leather bands, about 1½ ins. wide, each of such bands being provided with two metal studs (to penetrate the road surface) as well as two flat metal hooks,

ANTI-SIDE-SLIP TRIALS OF THE C.T.C.—The winning devices. The first prize was awarded to a non-skid formed by a narrow strip of rubber sewn in serpentine form to an ordinary pneumatic. See our article for details of above devices.

the awards. The Award Committee have apparently done everything in their power to ensure that their decisions shall form a reliable indication of the most suitable forms of non-skid among the 33 devices entered for competition. After the actual tests on the grease, the machines were given a road trial of some 400 miles, at the end of which the members of the committee personally experimented with the five devices which they considered most worthy of receiving prizes. As the result of these tests the following awards have been made :—

- First prize (£100) to Messrs. Bullard, Wilderspin and Adams.
- Second prize (£50) to Messrs. Grose.
- Third prize (£25) to Mr. T. J. R. Clarkson.
- Fourth prize (£25) to Mr. W. H. Robson.

The four devices receiving the above prizes we reproduce from the *C.T.C. Gazette*. The highest award was obtained by a smooth-treaded rubber tyre, on which was sewn a narrow serpentine band of rubber. In actual manufacture this band would, of course, be moulded on the tread. The report states that the resilience of the tyre was considerably reduced by the ridges, but that the side walls of the tyre might with advantage have been more flexible.

The Grose steel-studded leather band, which received second prize, is too well known to our readers to need description. Referring to this device in the report, the committee considered that fewer studs might be an improvement, both as regards resiliency and noise on paved roads.

Mr. T. J. R. Clarkson's device (third prize) has the merit of simplicity, for it is nothing but a number of small metal bolts

ANTI-SIDE-SLIP TRIALS OF THE C.T.C.—Mr. J. Kirkland's device (No. 19) consists of wire staples embedded, "business ends" up, in the fabric of the cover. This was one of eight devices chosen by the committee as worthy to take part in the final tests.

which gripped the beaded edge of the rim of the wheel, the tyre of which was then inflated. About eight of these bands were placed on each wheel, and so far as their non-slipping properties were concerned, they seemed to be equal to the best. Several bands broke on the trial spins, and on two occasions riders were thrown from their machines by the broken bands jamming in the brake or the mudguard. They interfere very little with the resilience of the tyre, and are, of course, inexpensive, but the Committee state that they cannot recommend them except for temporary purposes.

In summarising the result of this competition, which although conducted with ordinary cycles, must, nevertheless, be of considerable interest to all motorists, the judges remark:—"We think it but right to say that in so far as the discovery of a perfect and easily applied remedy for side-slip is concerned, the competition has not realised our hopes; it has, however, demonstrated the fact that the pneumatic tyre as commonly employed might be made less liable to side-slip if suitable (though more pronounced) corrugations or ridges were moulded on the tread somewhat after the manner of the device to which we have awarded first prize. Such a modification of the existing practice would admittedly detract somewhat from the speed of the tyre, but it would not sensibly diminish the comfort of the rider, and to the thousands who put safety before speed it could not fail to commend itself. No alterations of existing rims would be called for, and tyres already in use might be fitted with bands upon which the corrugations referred to might be moulded just as the Grose band, the second prize winner, is fitted."

Albert Brown Trophy.—Confined to members of the Motor Cycling Club, this closed event was run off on Saturday last under the auspices of the club. Under the rules all machines must be entirely British-made in every part. The distance of this "non-stop" run is 100 miles before lunch and 50 miles after, a minimum and a maximum time being allowed for each 50 miles run. The route of the trial was the London-Coventry road between Redbourne and Braunston. The start was made at 6 a.m., and during the first stage five of the competitors were eliminated, viz., Messrs. Hooydonk (Singer tricar), J. Bright (Rover), A. H. Bindoff (Rex), W. A. Jacobs (Rex), and B. Crump (Ariel tricar). Miss Hinde had carburettor trouble and stopped, but she was subsequently reinstated and continued the run. Twelve competitors took part in the after-lunch stage. It was necessary, owing to the number qualified at the finish, to hold the usual

special tests, subsequent to the 150 mile run, in order to determine the winner. These tests consisted of a hill climb, a speed test, and a brake test, which took place on a very severe gradient near to Redbourne village. Pedalling was not allowed, and the best performances in these tests were made by R. M. Bryce (Brown), J. Platt Betts (Rover), and E. W. Ashworth (Lagonda). Miss Muriel Hinde, on her Singer tricar, also scored well in the hill test. As a result, Messrs. Bryce, Betts and Ashworth tied in the bicycle class, Messrs. V. Riley (Riley tricar), and Wilbur Gunn (Lagonda tricar) being equal in the tricar section. It was, therefore, necessary to run off a further speed and brake test, in which Bryce was adjudged the winner, Ashworth second, and Betts third in the motor bicycles, and in the tricar class Gunn secured the first place, and Riley the second. Miss Hinde, as the only lady competitor, is to receive a special certificate for her very admirable performance.

International Cup.—The Moto Cycle Club of France are taking into consideration the proposals made by the Austrian Motor Cyclists' Union in connection with the alteration in the rules governing this Cup for next year, to which we have drawn attention in our recent issues. In the case of Mr. Klement's suggestion of limiting the weight of the motor only, and leaving the weight of the rest of the machine to take care of itself, it is suggested that the maximum weight for the motor should be 25 kilograms. The whole of the trade is to be circularised by the French Club in order to ascertain the views of the manufacturers throughout France upon these points.

THE Tour de France in 1906 for motor bicycles, under the auspices of the Auto Cycle Club of France, has been fixed to take place during the first part of May. The distance will be increased by 500 kilometres over the present year's course. The tour will be in the north and east of France before running from Dijon over the last course. The creation of a category for voiturettes has been agreed in principle.

THE Auto Cycle Club of France Cup, which is reserved exclusively for tourist motor bicycles with a maximum cylinder capacity of one-third litre, is to be held in July, 1906. It will be run over a 250 kilometre course.

MOTOR BOATING.

Burnham Motor Boat Meeting.—By an oversight, Mr. Robinson was referred to last week as the secretary of the Motor Yacht Club. Mr. Robinson is of course the secretary of the British Motor Boat Club which held

the trials, in which capacity he was responsible for the organisation and success of the meeting. We would also draw attention to the fact that the boat illustrated at the bottom of page 1,244 represents Mr. A. G. Fentiman's "Javelin"—not "Baby Brooke," as stated.

Motor Boat Measurements.—At the meeting of the Commission of the British International Cup at Arcahon, after the recent race for this trophy, which was won by Mr. S. F. Edge's Napier craft, it was decided that an allowance of 1.5 per cent. above all class limits is to be allowed in the length of the boats for future races. Therefore the length of the boats can be 12.18m. or 39 ft. 11½ ins., which will enable them to qualify for the 12m. class.

Messrs. Mawdsley Brooke "and Co." during an interval in racing "Baby Brooke" at the Burnham-on-Crouch meeting, which wound up the season of the British Motor Boat Club.

COUNT REVERTERA, accompanied by his chauffeur and a friend, for a wager, recently performed a motor run from the Rand to Cape Town, a distance of 1,200 miles. None of the trio were acquainted with the route, so that the ten days taken in accomplishing the performance can safely be said to constitute the run a good one, as considerable deviations were made through lack of knowledge. The Count drove his 6-h.p. De Dion-Bouton, which he had specially fitted to hold 18 gallons of petrol, receiving local supplies *en route*. Altogether the Count's little De Dion consumed less than 60 gallons from start to finish. The luggage, petrol, and spare parts totted up to some 700 lbs. in weight.

THE "SYRINX" SPRING TYRE.

QUITE the most drastic innovation which has yet come to our notice, in the way of mechanical substitutes for pneumatics, is the "Syrinx" spring tyre, put on the market by Mr. W. H. Robson. This is the device which has just secured the fourth prize in the C.T.C. Anti-skid Trials. No rubber whatever is employed in its construction, and, in fact, it has—in the accepted sense of the word—no tyre at all, because the numerous conical springs which project radially from the rim of the wheel, alone form that part of the wheel which comes directly into contact with the road surface.

The illustration shows a view of the rim complete, the photograph having been taken of a rim made for a motor bicycle. Within the rim is one of the springs for a motor car wheel, this spring having been photographed to the same scale as the complete rim. Below, are four larger views of one of the springs used on the rim shown above, and these serve to illustrate the construction and method of fixing which is adopted.

The springs, A, are made from steel bars of circular section and are wound in conical form ;

they are easily attached by a rivet to the spring-holders, A¹, while at the same time they are able—at their larger outer end—to obtain a good grip of the ground. The spring-carrier, A¹, is semi-cylindrical in form, and has the spring, A, riveted to it at the centre of its length. A closely-wound helical torsion-spring, A², fits into the holder, A¹, as shown, and is held in position by clips which are solid with the holder, and are bent over so as

The "Syrinx" Spring Tyre, fitted to an ordinary push bicycle.

to grip the spring, A². It will be noticed that the spring, A², is formed with an eye, A³, which is arranged to pass through a small slot in the rim of the wheel, and that there is a notched wedge, A⁴, which is pushed through the eye, A³, to secure the spring in position. When thus secured, the spring-carrier, A¹, is drawn tightly up against the rim ; a certain amount of play between these two members is, nevertheless, possible, because of the spring, A², which allows the carrier, A¹, to rock over bodily when any severe side strains are imposed.

The springs for cars are identical in design, except for the substitution of a bolt and nut fastening to attach the spring to the rim, instead of the wedge and eye device used on the smaller wheels.

Reference Letters.

A Springs.	A ³ Eye for attaching spring to rim.
A ¹ Spring holders.	A ⁴ Pin for securing spring in place on the rim.
A ² Torsion springs.	

THE SYRINX SPRING TYRE.—View of a rim complete with the Spring Tyre. Within the rim—which is for a motor bicycle—is seen a spring for use on the wheel of a motor car. Below, are four views of one of the springs fitted on the rim shown above, and these show the method of construction and attachment adopted.

More Motor Cabs for London.—A number of motor hansoms, in which the driver's seat is to be at the back of the cab—as with ordinary hansoms—have recently been ordered by the Metropolitan Motor Cab and Carriage Company. These vehicles, which are being built at Luton, will have a three-cylinder vertical engine of 12–14-h.p. placed beneath a bonnet in front, and not only is there to be ample room between the body and the dashboard for ingress and egress, but space is also being provided beneath the driver's seat for carrying luggage.

CORRESPONDENCE.

* * The name and address of the writer (not necessarily for publication) MUST in all cases accompany letters intended for insertion, or containing queries.

ENGINE BRAKING.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I think Mr. Edge raises an interesting point on the above question in this week's AUTOMOTOR JOURNAL.

I expect if he still further analyses his replies, he would find a large proportion of those in favour of clutch and brakes being entirely independent, would come from hilly districts.

I have always altered all my cars in order that I can use the engine as a brake, and in a hilly country like Dartmoor I think it is almost a necessity.

It is far easier to restart on a steep hill; your pump is always at work circulating the water used for cooling the engine, and there are many other advantages.

Mr. Edge mentions "with the ignition switched off," but I think the throttle should also be made to "cut right off," else you might get your silencer full of gas, and when you come to restart you may burst it—I don't say you would on a Napier, but you would on some cars I know.

I would take this opportunity, while writing to you, to congratulate you on your "Mercedes" articles, they are most interesting.

I hope you will give us some on the new 50-h.p. 6-cylinder Napier. I have a chassis coming in about three weeks, not geared very high, and I think it will be a very fine car, judging from a trial run I had on one some time ago.

Your articles are most instructive and show up points that the ordinary motorist does not grasp at first sight.

Yours truly,
RICHARD BAYLY.

October 7, 1905.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—We have been extremely interested to read Mr. Edge's remarks anent his new discovery that using the engine as a brake, with all friction brakes independent of and supplementary to it, is the right thing. The thanks of the motoring public are due to Mr. Edge for having discovered it, although we may remind your readers and Mr. Edge that we discovered it many years ago, and have for the past four years been selling Duryea cars in this country so fitted, and have been strenuously advocating the system throughout the whole of that time. Although, therefore, Mr. Edge's discovery is nothing new—to us and users of Duryea cars—it is, nevertheless, one of some value to those who have hitherto discountenanced the system. Now that Mr. Edge says it is right, we have no doubt that that large portion of the public who accept as correct only that which is favoured by the manufacturer of a racing car, will now come to believe that, after all, Duryea was right, and that "experts," whose only idea runs in the groove of "What is, is right," may yet come to see that principle of construction which are not found on every Continental car, and have not hitherto been used on racing vehicles, may still be right.

If the conversion of Mr. Edge to correct principles, after so long an adherence to incorrect ones, has the effect of altering the construction of cars in this important particular, it will be the better for the safety and convenience of the motoring public, and although we may lose our position of monopolists in this, as in so many other particulars, we may perchance find ourselves "in the fashion," and it may even yet come about—when they are discovered by Mr. Edge or some equally prominent manufacturer—that other of our present unique principles, although differing from the "car in the street," may still receive the approbation of the "expert."

Yours faithfully,
THE DURYEA MOTOR COMPANY.

October 7th.

LONG DISTANCE RUNS ON TOP GEAR.

IN view of the interest now taken in cars that can travel long distances without changing gear, the Anglo-American Motor Car Company write us upon the subject, enclosing a copy of the following letter that they have received from a user of one of their well-known single-cylinder vehicles:—

GENTLEMEN,—As there appears to be a lot of talk just now of cars making long runs on the high gear, we thought it might interest you to know of a run we made on a Standard 8½-h.p. Cadillac Model F.

After viewing the Tourist Trophy Race, we started from Chester to make the run home (Harrow), via Wolverhampton and Coventry; we accomplished this journey (176 miles) quite comfortably in exactly

8 hours, using the high gear the whole of the distance. This, as you will see, averages 22 miles per hour, although we had to "crawl" through a police trap of about 3 miles. We might also state that we used 5 gallons and one pint of petrol, which works out at just over 34 miles to the gallon. We think this a very good performance, as the car was not prepared in any way, having run about 2,300 miles previous to this without requiring adjustment. We carried four passengers and luggage during the above run.

Yours faithfully,
A. RUFFELL.

September 27th.

"PRIVATE" ADVERTISEMENTS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Our attention has been called to the fact that an advertisement has been appearing recently in "The Automobile Club Journal," under the heading "Members' Private Advertisements," and also in the general Press. This advertisement offers for sale one of our cars which purports to have been built for H.R.H. Princess Christian.

As a matter of fact, neither the chassis nor the body of this car as advertised were built, or intended, for Her Royal Highness, and the impression which has got abroad very generally among members of the trade, as well as among private individuals, that Princess Christian has ceased to use our car and has thrown it upon the market is calculated to do us a great deal of harm.

As a matter of fact, Her Royal Highness has recently been on a tour in our car in the West of England without the slightest trouble, and has expressed herself as extremely pleased with it.

We are taking up the business very strongly with the firm of coachbuilders who have lent their name to this advertisement, as well as the owner of the car, who presumably is primarily responsible.

We trust that, in justice to ourselves, you will afford a little of your valuable space to call attention to this matter.

Yours faithfully,
JOHN I. THORNYCROFT AND CO., LIMITED.

October 9th.

GREAT BRITAIN AND AUTOMOBILES.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Mr. Edge is exceedingly unfair and unjust in his remarks in your last issue as to the position of those gentlemen who are solely interested in the importation of French-built cars into England.

I think the point which he has always argued upon has been as to the quality of construction rather than the sales of imported and home manufactured vehicles.

Everyone connected with this industry in England—whether they are concerned in the importation of foreign vehicles or not—must be gratified at hearing that England—and London in particular—is becoming the great hub and centre of the world's motor industry. I take it that it is the wish of everybody that this should be so; that all buyers should come to London whether they be purchasers of foreign vehicles or home manufactured cars.

I would like to point out that it is owing to the necessity of meeting foreign competition that British-built vehicles are as good as they are to-day, and to suggest that Great Britain is belittled because one does not accept as gospel everything one is informed by those who are engaged in the sale of British cars, strikes me as not only being small-minded, but foolish.

As being, like Mr. Edge, largely interested in the sale of foreign-built automobiles, I view with the greatest satisfaction the fact that the buying public do not now consider it necessary to go to Paris to place their orders for cars, but can make their selection—and do make their selection—of whatever make it may be, foreign or otherwise, from the London showrooms.

Yours faithfully,
CHAS. JARROTT.

October 10.

WE have received a letter from Mr. W. J. Seaton asking for information about a matter of personal interest and have, in accordance with our usual practice, replied to him by post. Our letter has, however, been returned by the Postal Authorities marked "unknown" at the address given by him.

THE Government of the French Republic are following the example provided by Ministers in Great Britain in appointing a Commission to consider what modifications of the laws regulating the motor traffic may be regarded as desirable.

AERONAUTICS.

ANOTHER example of the manner in which (almost it would seem purposely) the fury of the elements is wreaked upon constructions designed for navigating the atmosphere is provided by the unfortunate accident which occurred to Mr. Marinahis's airship, which has been constructed by Messrs. Braun & Co., of King's Cross, in a shed on open ground at North Greenwich. The airship, of the navigable balloon type, which was practically complete in every particular, was to have been officially inspected by Col. Temple on Friday in last week, but on the previous Thursday, about one o'clock, a violent storm of wind and rain, sweeping across the exposed ground at Greenwich, shattered the shed containing the airship and reduced the machine to tattered fragments in a short period. The ruin is believed to be absolutely irreparable, and a new machine, which will present several "novel features" in aeronautical construction, is shortly to be commenced by the intrepid experimenters, who possess what appears to be one of the leading characteristics of all who are at present assaying the conquest of the atmosphere—undauntedness.

ONCE more the Lebaudy airship has arisen, we cannot say from its ashes, but from the very severe wreck which was made of it in the summer by the tempest in the moment of its victorious arrival at the camp of Chalons. It has been thoroughly repaired, and gone up again in the presence of M. Berteaux, Minister of War, and under the guidance and management of the official military aeronautic expert, Captain Voyer, who, with another officer, got into the car. Though there were torrents of rain and a high wind, the airship behaved magnificently, battling its way against the storm, maintaining a regular altitude of 200 metres, and after a variety of complicated evolutions, ultimately descending at the very spot previously arranged upon.

The Olympia Show—the King a Patron.—The coming Exhibition of the Society of Motor Manufacturers and Traders at Olympia, which will be held from November 17th to the 25th, promises to be a more brilliant affair than any that have preceded it. First and foremost, His Majesty King Edward has this year consented to become Patron of the Exhibition, and the patrons accordingly now number not only His Majesty and the Prince of Wales, but the Dukes of Sutherland and Buccleuch, the Marquis of Ripon, Earl Amhurst, Earl Brownlow, Earl of Craven, Earl Fitzwilliam, Earl of Latham, and the Earl of Wilton. As already announced, the Olympia building itself has undergone considerable modification and extension, and every foot of the available exhibition space has for a long time past been engaged. There will be upwards of 300 exhibitors, of whom no less than 104 will be motor car dealers who are exhibiting complete vehicles, 35 will have commercial vehicles and delivery vans on show, and 26 will display motor bodies, the remainder being divided between carriage work, tyres, accessories, and machinery exhibits. As we recently had occasion to observe, statistics of the motor car industry show that the English market is the great market of the Continental manufacturer, and the international character of the exhibition will accordingly be well represented, no less than thirty-six foreign firms showing in the motor car section, and nine in the motor boat division. As French and other foreign manufacturers will be exhibiting their 1906 types, English buyers will not be compelled to wait till they are able to visit the Paris Salon in December before they are able to make up their minds as to what type of French or Continental car they desire to purchase. Preparations for the motor car exhibition will commence as soon as the Electrical Exhibition at present being held at Olympia concludes, on the 25th instant, and the decorations, lighting, and general effects will, we anticipate, in accordance with the great development of the Olympia Exhibition, be probably even more attractive than they were last year.

The new show-rooms of "Argylls, London, Limited," at 17, Newman Street, Oxford Street, where accommodation is available for 40 cars at one time.

Mr. Phillip Wilkins on his new 28-36-h.p. Daimler Car. Mr. Wilkins is an enthusiastic motorist, and his previous experience with a smaller Daimler vehicle has led him to again select the same make when ordering a more powerful car.

The Royal Agricultural Show.—There will be no exhibition at Park Royal next year. The edict has gone forth as the result of a recent committee meeting, held under the presidency of Mr. F. S. W. Cornwallis, at which numerous questions affecting the organisation and control of the Society were brought up for discussion. No one will be surprised at the decision, for the permanent showground has always proved a dismal failure financially. The Park Royal show was the only representative exhibition of automobile machinery exclusively applied to agriculture, and it is somewhat to be regretted that it is no longer to be held as a fixture in the vicinity of London. But as it has been ordained by the committee that the Society shall be restored to its peripatetic state, possibly this branch of automobilism will gain more by being brought to the closer notice of agriculturists in the provinces than it will lose from other causes. At any rate we hope this may prove to be the case.

Cost of Upkeep of a 12-h.p. Car.—Actual figures, showing how much it costs a motorist to keep a car, are always of value, the latest to hand being contained in a letter written by Mr. D. Losh Thorpe, of Carlisle, on the subject, after he had had his car for a year. After stating that he had experienced three punctures during the entire twelve months, but had never been stopped or delayed through mechanical troubles, he gives the following particulars of the car's performance. The total mileage amounted to 3,173½ miles, including a very wet fortnight's tour of 1,033 miles to John O'Groat's and back, and the total fuel consumption was 170 gallons. This works out at a mean consumption of one gallon for 18·7 miles. The total running expenses, leaving tyres out of consideration, is stated to have been £10 7s. 6d., which is equivalent to 785 pence (a little over three farthings) per mile. The car with which these very satisfactory results were obtained is a 10-12-h.p. Argyll.

Justifiable Retaliation.—We really feel quite unequal to doing justice this week to the number of cases more

or less absurd, and nearly all of them more or less prejudiced and unjust, in which motorists have been arraigned and, of course, fined, before Petty Sessional benches. Andover is of course still in eruption, Knaresborough is still nagging away, and St. Neots has been so annoying to several victims that revenge has been taken on the magistrates by demanding that they should be compelled to state a case, while the Motor Union is supporting an appeal to Quarter Sessions. In the meantime a well-known motorist and local magnate has taken a line which we would like to see generally adopted and which would go a long way towards taking the bloom off the peach which local authorities have discovered in the contributions to the rates extorted from automobilists. Mr. Leycester Barwell has fallen into the hands of magistrates and their "highwaymen," and has been mulcted in fines for the merely technical offence of exceeding the speed limit. He has hitherto been a liberal subscriber to local charities and other public objects,

but now when he is asked for a subscription he sends out the following circular in which the feelings of the unjustly condemned peaceable motorist are admirably expressed in a single comprehensive sentence:—

"As a victim of police persecution and a system of legalised robbery by police and magistrates, and having paid exorbitant fines and costs for the purely technical offence of exceeding the legal limit of speed by a few miles an hour on straight and practically deserted roads, timed with cheap stop-watches in the hands of interested prosecutors, whose only object was a conviction with heavy fines and costs (the offence of leaving a horse-drawn vehicle unattended on the road, or of being asleep when supposed to be in charge of same, being met by fines of half a crown or five shillings, should the police take the exceptional course of prosecuting), I am reluctantly compelled to withdraw my support from all charities, local and otherwise, including my usual subscriptions to the church, hospitals, and other deserving institutions."

AMONGST the cases referred to above must be mentioned those of Lord Alwyne Compton, M.P., and Capt. Grenfell. Both of these gentlemen fell into the same police trap along the Marylebone Road, and both, by one of those marvellous coincidences with which police traps have rendered us familiar (and upset the computations of mathematicians familiar with the calculus of probabilities) were going over the same stretch of road, at two different hours on the same day, viz., September 17th, at exactly 26 miles an hour, not a yard more and not a yard less. Lord Alwyne Compton, M.P., fell into the hands of Mr. Plowden, who happened to be the "sitting" magistrate on the day his summons was heard, and Mr. Plowden being one of the best tempered and most progressive of London magistrates, let him off with a fine of 40s. and 2s. costs. Capt. Grenfell was not so lucky. He encountered Mr. Paul Taylor, a magistrate of a different stamp, and for identically the same offence of travelling at identically the same speed (so swore the constables) at identically the same place on identically the same day, was fined £10 by the other magistrate. It is a sad commentary on justice's justice.

Examinations for Driving and Mechanical Proficiency Certificates.—Examinations will be held by the A.C.G.B.I. at the following places during October:—

Coventry	Monday, Oct. 16th	Daimler Works.
Birmingham	Tuesday, Oct. 17th	Grosvenor Cloak Room, Grand Hotel.
Manchester	Wednesday, Oct. 18th	Midland Hotel.
Sheffield	Thursday, Oct. 19th	Cutler's Hall.
Nottingham	Friday, Oct. 20th	University College.

A Motor Lochinvar.—To carry off your bride more or less *vi et armis* has appealed to the impassioned lover in all ages, and the automobile certainly provides the *vis* if not the *arma*. At any rate, that appears to have been the opinion of Lord Malden who, by means of a motor car, carried off Miss Eveline Freeman from the old Manor House at Wingrave, and married her within a few hours of the elopement, which commenced at six o'clock in the morning. The bride, immediately after the function, sent a wire to her parents, which possessed the classic brevity of the "Laconic Apothegm," to wit, "Married Lord Malden to-day—Eveline." This is certainly an up-to-date edition of the episode by which old Haddon Hall came into the possession of the Manners family. An element of romance which was wanting was due to the circumstance that there was no pursuit.

"There was racing and chasing on Cannobie Lea," and the good old Gretna Green marriages were usually celebrated a few miles in front of an irate father or brother who was pursuing in fury and a coach-and-four. When next there is an automobile elopement, we trust the stage managers will arrange to make this romantic ad libition, after which there will be room for another Scott to write a "Motor-Lochinvar."

MESSRS. PHILIP, SON, AND N have forwarded to us for inspection Maps of England and Wales. The four handy sheets mounted on line 4 miles to the inch, and are won main roads being indicated with distinctness. The four are enclosed designed for fixing on the dashboard provided with an internal spring which is opened, raises the maps in a convenient position for removal and consultation. Each map is very sensibly mounted on side of the linen backing, so as to do the size of the sheet, and the whole ought to render it almost superfluous for any motorist provided with them to ever have to ask his way, at any rate as far as the main roads are concerned. In one or two cases where we have been able to test the correctness of the by-roads, the maps, owing presumably to topographical alterations due to the lapse of time, may leave a little to be desired. But for the purposes of the ordinary motorist the maps certainly appear to be all that can be wished for.

THE President of the French Republic has extended his patron-

age to the International Congress on Automobile Touring and the controlling of automobile traffic on the roads, which is to be held in Paris in December in connection with the Paris Salon.

AN amusing case of how a motor 'bus came to the assistance of a police detective was recorded in the daily papers last week. The detective was about to arrest a gang of male and female pickpockets in the Edgware Road, when they gave him the slip into the underground railway station. Knowing the habits of his prospective prey, the detective anticipated that they would emerge at Baker Street. On to a motor 'bus which was just starting, and for once was not packed full, he accordingly jumped with promptitude, and alighting at Baker Street Station, was successful in arresting the miscreants as they emerged into the street.

A SOMEWHAT different example of a case in which the automobile came to the assistance of the police and the discomfiture of a certain poacher is reported from the neighbourhood of Kettering, where one Marlow, who had been "trespassing in pursuit of game" and had been sentenced to a month's imprisonment, escaped from the constable in charge of him, slipped his handcuffs and ran off. The constables in pursuit commandeered a passing motor car, finally captured the poacher, and safely conveyed him to Northampton prison. The poacher had previously challenged one of the constables to run him a race for £5. Doubtless he regards the way in which the constable interpreted this wager as an unfair handicap.

The above new pattern of the British Duryea Car has just been placed on the market. It is a 12-h.p. vehicle, and the tonneau at the back is constructed to hold three passengers. This particular car has been secured by Dr. J. D. Mackay, of Knaresborough, who has for the third time selected a vehicle of this make.

THE town of Bradford has always been a progressive centre, and we have already referred to the arrangements of the Bradford Technical College for providing a motor car engineering course for students. The first of the lectures was given on Wednesday in last week by Professor G. F. Charnock, an introductory discourse being delivered by the Mayor, who certainly recognises more than a good many corporation officials what the motor vehicle is destined to effect. The future development of the motor vehicle and the motor 'bus means, in his eyes, "a much cleaner Bradford than exists to-day," and he regretted that "classes such as those which Professor Charnock was now conducting had not been inaugurated some ten years ago." In that case, he thinks, "local progress would have been very much more marked than it has been."

A side view of one of the London and North-Western Railway omnibuses now in full service in Wales. These vehicles are built by the Milnes-Daimler Company, and are of similar construction to the London "Vanguard" motor 'buses.

THE Swiss gendarme and his men who happened to catch Mr. Rockefeller driving an automobile over the prohibited Tête Noir Pass are to be congratulated. Mr. Rockefeller not only immediately paid the heavy fines imposed, but entertained the gendarme and twelve men who had been commandeered to assist him, to a sumptuous dinner, a custom which is hardly likely at present to spread to the British Islands. An amusing feature of Mr. Rockefeller's adventure was that after his car was stopped and himself arrested, the police officers actually refused to allow the car to proceed further under its own power, and commandeered eight horses and the twelve men above referred to, to bring the car, together with its occupants, back to Martigny.

THE inhabitants of Eton, as becomes a town associated for so long with such an ancient foundation as the college at which most of our leading aristocrats and statesmen have been educated, and upon the playing fields of which, according to the "historian" Kinglake, the battles of Alma and Inkermann were won, is very conservative in its tendencies, and a letter has been written to the daily papers by a correspondent entitling himself "Pater Etoniensis," bitterly complaining of the noise and rumble of the motor 'buses which the Great Western Railway Company has organised to run through the town. He calls upon the authorities to insist that they shall be of moderate size and noiseless mechanism. There is something, perhaps, in the contention considering the associations of the place, though how a local authority can insist on such a provision by any means but friendly representation, it is difficult to see.

MOTORISTS are informed that the cyclist patrols of the Automobile Association will be on duty next week end from Purley Corner to Preston Park on the Brighton Road, and from Kingston to Hindhead on the Portsmouth Road. They are to be distinguished by a yellow armlet, bearing a number, and the letters "A. A.," and their instructions are to render assistance to all motor car and motor cycle drivers, whether members of the Association or not.

A Foden lorry, one of many motor goods vehicles now being employed by the London and North-Western Railway Company, in various districts, to deal with the enormous haulage business in outlying districts which the Company are developing by this means. This particular lorry, put on in July, runs between Holywell Station and the town. Holywell lies at the top of a very steep hill $1\frac{1}{2}$ miles from the station, and hitherto the average weight taken by a pair-horse team has only been 13 cwt. The new steam lorry is capable of taking 5 tons, and also a trailer with a capacity of 2 tons. So far, there has been no failure of any kind, and the daily weight carried has averaged from 15 to 18 tons. The distance covered is from 18 to 19 miles, or three complete journeys daily.

THE Mersey Railway Company is keeping pace with the other great railways in this country by establishing a road service of motor 'buses to feed their railway traffic. Ten 'buses, we understand, are now on order for the railway company, and of these four will be delivered within the next month. In general outline and appearance they resemble the "Vanguard" type of 'bus with which Londoners (with the exception of Mr. Plowden) are now so familiar.

A WAIL is wafted to us from across the Weald. That august body, the Cuckfield Rural District Council, laments that it is not so easy to obtain restriction of the speed of motor cars to ten miles an hour as they could wish. "The Local Government Board," it was stated, "put every obstacle in the way of County Councils obtaining such orders." The two applications that have been made by the East Sussex County Council have strained the finances of that august body to such an extent that they have (regretfully) announced their intention of not making any further applications. How sad!

FROM the *Board of Trade Journal* we learn that the *French Commercial Adviser* at Helsingfors reports that the "use of automobiles has for some time past been increasing in the large towns of Sweden, such as Stockholm and Göteborg." This is interesting information, though it comes by a somewhat roundabout route (not unusual) to the *Board of Trade Journal*, in the first place being from a French source, while in the second place, Helsingfors is not in Sweden at all, but is the capital of Finland. According to the French Adviser's report the best automobile markets in Sweden are the two towns mentioned, together with Malmö and Norrköping. In the north of Sweden and Finland, where the roads are not so good (as most of the traffic is done when they are covered with snow), motor bicycles are in demand, though the price which it is said they fetch, viz., £16 to £24, must be regarded as extremely moderate. For motor boats, too, on the rivers and lakes of Sweden those who are willing to sell them at from £55 to £165 will find a market.

THE *Board of Trade Journal* also calls attention to the report of the *Belgian Consulate* at Bombay. The Belgian representative points out that an extraordinary increase has recently been taking place in the number of automobiles imported into India. They are becoming increasingly popular with the native population, and in Bombay in particular, all kinds of self-propelled vehicles find a ready market, while motor cycles also seem likely to come rapidly into use.

THE first Smoking Concert of the Automobile Club takes place on the 26th inst. The club is also arranging to continue the series of evening discussions on automobile topics.

THE RIGHT HON. THE EARL OF EFFINGHAM has consented to become the President of the Sheffield and District Automobile Club.

WE are constantly receiving fresh indications of the out-of-the-way places that THE AUTOMOTOR JOURNAL finds its way to. A couple of amusing instances have been drawn to our attention by Messrs. Jarrott and Letts, one of whose correspondents, rejoicing in the name of Kofi Bu, writes from Adjah Bippo to the firm in quaint language, asking details of their cars advertised; while another, who signs himself "M. Thomas esq.," writes from Kissy, Sierra Leone, as follows:—

DEAR SIRs,—Having heard of your valuable etc. as I was reading a paper that I find in the Public way, as am reading it, then I turn the Bark of it, I saw your address on it then I said I will send for your catalogue. May you send me one of your Catalogue? Believe on me yours very Faithfully,

M. THOMAS, esq.

THE ROTHWELL DELIVERY VAN.—Among the firms who have most recently turned their attention to the construction of light commercial vehicles is the Eclipse Machine Company, who are now building one hundred delivery vans, similar to that illustrated. The frame is of armoured wood, although pressed steel will be used in future. The engine is a 12-14-h.p. Aster, and the chassis, which is of the live-axle type, is fitted with a three-speed gear-box, the gears being operated by a horizontal lever fitted on the steering column immediately below the wheel. We understand that the Company make a rule of sending an efficient mechanic with each van delivered, so that the prospective driver may receive a week's tuition prior to taking sole charge of the vehicle.

UNDER the rules of the National Association of Automobile Manufacturers in the United States, all automobile shows must receive their sanction and licence before they can be recognised by the Association. Non-compliance with this requirement penalizes all exhibitors at an unlicensed show from exhibiting at any of the licensed shows of the Association. Under this provision it was necessary, therefore, for the Automobile Club of America to obtain a licence from the Association for their "independent" show, which is to be held in the 69th Regiment Armoury, New York, as announced by us some time ago. Several of the Club authorities were averse to asking for this permission, but it was found that the firms who wished to enter for the show were too shy of getting into trouble by exhibiting without the protection of the necessary permit.

COMMERCIAL POINTS.

MOTOR cars were requisitioned to convey the Viceregal party on the recent tour in Ireland, one of which, the Clement, went through the whole trying journey without any mishap whatever. The Right Hon. John Atkinson, the Attorney-General, was particularly pleased with his experience throughout the run.

WE learn that the Continental Tyre Company propose holding a tyre-fitting competition at the forthcoming Olympia Exhibition. It will be remembered that they instituted a similar competition at the Olympia Show last year, which proved very popular, a large number of entries being received.

MR. SIDNEY STRAKER desires to give notice that he has no connection with any other firms in the motor omnibus and commercial vehicle trade other than Straker and Squire and the Straker Steam Vehicle Company, Ltd., of 9, Bush Lane, E.C.

During his recent visit to Guernsey—where he inspected the defences of the island and unveiled a South African War monument—H.R.H. the Duke of Connaught made use of the 18-22-h.p. Climax Car, seen above. The vehicle in question, which only arrived shortly before the Royal visit, was kept in commission three whole days, during which time it ran without a hitch, and appeared to give great satisfaction. It is of the live-axle type, has a 4-cylinder Aster engine, and was built for Mr. F. A. Heyl, who is, we learn, the principal motor car dealer in Guernsey.

WE regret to hear that the wife of Mr. T. W. Staplee Firth is lying dangerously ill at their residence, Upper Tulse Hill.

THE St. Neots trap, which is situated in or near the village of Buckden, is in a state of great activity, and no less than six members of the Motor Union have consulted the Secretary in regard to summonses which they have received. As a result, the Motor Union has decided to assist two of them, and Earl Russell has been briefed to appear for them before the St. Neots magistrates on the 17th instant. In addition, the Motor Union are also arranging to accord their support to an appeal to Quarter Sessions which has been lodged by one of the previous victims of this Bench, whose notoriety is now almost rivalling that of Andover itself.

ANOTHER case in which a successful defence was made on behalf of a motor omnibus, in which the charge was that of not consuming its own smoke as far as practicable. This was heard before Mr. Lane at West London Court last week. The motor 'bus belonged to the London Road Car Company, and evidence was given by the company's chief engineer, Mr. Brackenbridge, to the effect that the construction was such as to consume the smoke and that its emission was a pure accident. On Mr. Lane observing that the Council who prosecuted had called no expert evidence, their legal representative maintained that the onus of disproof rested with the defendants. "Yes," said Mr. Lane, "and they have done it satisfactorily," and he dismissed the summons with costs.

M. DUCELLIER has been awarded a Grand Prix for his well-known motor specialities at the Liege International Exhibition. This, we learn, is the first time that such a high award has been given in any exhibition for this class of manufactured article. M. Ducellier, who holds a very important position amongst manufacturers on the Continent, has usually been chosen in international exhibitions as a member of the jury, but we learn that for the Liege Exhibition he purposely declined the honour, in order to allow for once an international jury to judge his own goods, with the above gratifying result. Mr. Andre A. Godin, of Red Lion Square, W.C., is fortunate in handling M. Ducellier's goods, he being the sole exclusive agent in this country for the Ducellier motor lamps.

RECENTLY we announced that a number of 60-h.p. Mercedes chassis had been purchased by the proprietors of the Motor House, Euston Road, and that the occasion afforded an opportunity for those who were desirous of obtaining one of these famous machines. We now learn that already, with the exception of two only of these vehicles, the whole lot have been disposed of, amongst the latest to secure chassis being Mr. A. D. MacNeill, of Malling, Lewes, and Mr. D. T. Brown, of West Kirby, Cheshire. Both of these were the same model as that which the Duke of Manchester recently obtained from the Motor House.

A smart 12-h.p. car, recently built by the Swilt Motor Company, Limited, and supplied by them to the Warwick Tyre Company, Limited, for business purposes. The car is luxuriously fitted throughout and the Cape cart hood extends from end to end.

CLUBS AND ASSOCIATIONS.

Yorkshire A.C.—During October an interesting function is to take place one evening at the club headquarters in Leeds in the form of a presentation to Mr. L. Hey, the hon. secretary of the club, in commemoration of his recent marriage. Another pleasant meeting will be upon the occasion of the presentation of an illuminated address, signed by all the officers of the club, to Mr. H. R. Kirk, in recognition of the great hospitality to the members of the club and their friends upon the occasion of the first club run of the season to Windermere, when nearly one hundred members and friends were present.

A FURTHER lengthy list of makers and agents who have sent in returns to the Society of Motor Manufacturers and Traders for the purpose of the Royal Commission on the Motor Car Acts, has been received, enabling the Society to further add to their splendid list of statistics previously obtained. All those directly interested in the industry who have not already made returns should do so without a moment's delay, as the Commission commences sitting next week.

THE Ilford and District Motor Club have changed their name to the West Essex Automobile Club.

AN important departure is being made by the English Darracq Company, who we understand have secured very extensive premises in Lambeth, for the manufacture of the Darracq car.

NEGOTIATIONS are in progress whereby the Sirdar Rubber Company propose acquiring from Messrs. Applegate, of Greenland Mills, Bradford-on-Avon, their premises for the purpose of establishing a rubber tyre factory in that ancient centre of the cloth industry.

BRITISH EXPORTS AND IMPORTS OF MOTOR CARS, &c., FOR 1905.

NOTE.—For 1904 comparative figures see full table for the year in our issue for January 21st, page 91.

NEW COMPANIES REGISTERED.

Argylls (London), (Limited), 17, Newman Street, Oxford Street.—Capital, £20,000 in £1 shares. Object, to enter into an agreement with Argyll Motors (Limited), to act as selling agents for that company in London and elsewhere. First directors, E. H. Watson (chairman and managing director), W. A. Smith, and A. Govan.

Alfred J. Farrah (Limited).—Capital, £1,500 in £1 shares. Object, to acquire the business carried on at 9, George Street, Hull, as Alfred J. Farrah, of motor and other cycles, cars, &c. First directors, A. J. Farrah, Mrs. J. Farrah, and W. R. McBride.

Motor Roads (Limited) (Guernsey Company).—Capital, £150,000. First directors, G. W. Breffit, S. Barber, G. Shenton, R. Jarvis, A. Smeed, H. C. Potts, and F. E. Potts.

New Arrol-Johnston Car Company (Limited).—Underwood Road, Paisley.—Capital £100,000 in £10 shares. Object, to acquire and carry on the business of the Mo-Car Syndicate (Limited). (Scotch Company.)

Pneumatic Piston Tyre Company (Limited).—Capital, £60,000 in £1 shares. Object, to acquire certain patents for pneumatic tyres, and to adopt an agreement with F. G. McKim and J. M. Lennard. First directors, C. E. De Wolf, W. C. Clark, J. Todd, and J. F. W. Lennard.

The Suburban Motor Omnibus Company (Limited), Richmond Place, Main Street, Wishaw.—Capital, £2,000 in £1 shares. (Scotch Company.)

Quite recently (on Sept. 16th), we gave an illustrated description of the very well-considered automatic lubricator, which the Albion Motor Car Company are now manufacturing, and are fitting to their own cars. The photograph reproduced above shows a complete lubricator of this type, a working model of which can be seen at the London showrooms of the sole concessionaires in England and Wales for Albion Cars.

Omnibus "Cow-Catchers."—A most unfortunate accident occurred recently in the Charing Cross Road, when one of the employees of the Alhambra in attempting to get on to an ordinary horse 'bus fell into the road, and was caught by one of the Vanguard motor 'buses, suffering injuries to which he subsequently succumbed. The coroner's jury which considered the case absolved the driver of the motor 'bus from all blame, and suggested that in future "cow-catchers" should be employed on the fronts of motor 'buses. To this the coroner objected that their presence would be likely to enable drivers and others to claim an exoneration to which they would not be otherwise entitled—a view with which we certainly cannot agree, as no motor driver would ever rely on the "cow-catcher" to prevent an accident. He would in any case do his best, but when his best failed the "cow-catcher" might just make the difference between survival and death.

A NEW garage and repair works, fitted with all modern appliances, has, we learn, been opened in Brighton, under the title of the North Brighton Motor Garage, at Park Crescent Place. The premises are to be open day and night for repairs, and efficient workmen will always be ready on the premises.

POLICE PROCEEDINGS.

Motoring Schools and Premiums.—George Stephenson, 27, described as an engineer, of Royal Avenue, Chelsea, was last week charged, on a warrant, before Mr. Curtis Bennett, with being concerned, with another man, not in custody, in fraudulently obtaining premiums from young men, under pretence that he would teach them the motor car business and find them situations.

When apprehended by Detective Cock, and told that young men complained that sums of five guineas had severally been obtained from them, prisoner said he had not conspired, but had been co-partner with one Allen Glen in the Buckingham Gate Garage and Engineering Company.

Cross-examined by Mr. Wildey Wright, appearing for accused, the officer said he understood that some of the complainants had received lessons, and he was not aware that Stephenson left suddenly for the country to obtain money to satisfy a claim for which the sheriff had levied.

Inspector Fuller asked for a remand, as the police hoped to make another arrest. There were altogether about twelve complainants.

Mr. Wildey Wright said there was an absolute answer to the charge. Within the last two months defendant had expended £500 of his own money in satisfying the liabilities of the company. Defendant could not go on with the lessons to pupils as arranged, but he intimated that they would be resumed.

Mr. Curtis Bennett remanded the accused, stating that he would accept bail in £100, with notice to the police.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

23064. 26th October, 1904. Improvements in Internal Combustion Motors. James Dunlop, 69, Armadale Street, Dennistown, Glasgow, and Messrs. Kynoch, Ltd., Lion Works, Witton, near Birmingham. This invention relates to that class of motor in which oil vapour mixed with air forms the combustible charge. The oil to be vaporised is supplied to an outer chamber along with a small quantity of

lifted, and the lever, W, will then be unable to open the vapour valve, J, and thus the engine speed will be reduced again owing to want of vapour to keep it in action until the governor will fall, and by the insertion of the die, L, will enable the lever, W, once more to operate the valve, J. Operated by the lever, K, acting through the medium of a bell-crank increases beyond the normal the die, L, will be

top pivot pin, p_1 , is adapted to rotate within the hollow boss, q , of the bevel pinion, r , which gears with the pinion, j . The boss, q , of this pinion is rotatably supported in the bracket, s , carried by the axle, a . Attached to the boss, q , of the pinion, r , is one part, t , of a slide, the other part, u , of which is secured to the steering-wheel spindle, v . The steering-wheel, w , rests on the top of the steering-pillar, x , which is carried by the frame. The slide, t , allows of relative vertical motion between the steering-wheel spindle and the pinion, r , but forces the pinion, r , to rotate with the spindle, v . Consequently, when the steering-wheel is rotated, rotary motion is given to the pinion, r , and transmitted by it to the pinion, j , which being held from axial movement in the bracket, m , gives an endwise motion to the steering-rod, g . This, by means of the arms, e , and link, f , gives angular movement to the two steering-wheels. The parts, t and u , of the slide are made an easy fit one with the other, so that it not only allows of relative axial motion between the pinion, r , and the steering-wheel spindle being put slightly out of line with the axis of the pinion, owing to the jolting and vibration of the axle.—September 20th, 1905.

air, and owing to the heat transmitted through the walls from the inner chamber the oil is vaporised without the necessity of using a lamp except when starting the motor. Between the outer and inner chambers is placed a valve which opens towards the inner chamber to admit the oil vapour and air to the combustion space of the motor. The inner chamber constitutes the ignition apparatus of the motor, the heat generated by combustion being such as to maintain the surfaces of the chamber walls at such a temperature that ignition of the charge takes place by contact with these surfaces when and so soon as the charge has had a certain temperature imparted to it by compression. Water is admitted to the cylinder and forms part of the working charge with the object of controlling the time of ignition. There are two figures. Fig. 1 is a vertical sectional elevation of the rear part of the engine. A is the motor cylinder with the admission valve, B, and exhaust valve, C. These valves are operated by any usual means. The vaporiser, D, is placed at the back end of the combustion space, E, and has an outer chamber, F, provided with an oil feed bypass valve, G. The inner chamber, H, has a vapour valve, J, opening towards the combustion space, E, this valve being operated by a lever, K, through the medium of a die, L, and a reciprocating lever, W, with attached knife edge which engages with the die, L, and opens the valve, J, whenever the governor, M, is in the lowest position, that is when the engine is running normally. When the speed

lever, Z, are an oil pump, N, and a water pump, O, and at such times as the vapour valve, J, is rendered inoperative these pumps will be inoperative also. The oil pump delivers oil to the by-pass feed-valve, G, by a pipe, P, any surplus oil being returned to the pump suction tank by a pipe, Q. The water pump delivers water to the by-pass feed-valve, R, attached to the air admission valve chamber, any surplus water being returned to the pump suction tank by a pipe, S.—September 20th, 1905.

6196. 23rd March, 1905. Improvements in Steering Gear for Self-propelled Vehicles. Messrs. Beyer, Peacock and Co., Limited, Gorton, Manchester, and Henry A. Hoy, General Manager of the Company. The object of this invention is to cause the non-rotating axle to take up the shocks transmitted along the steering rod, which shocks are caused by irregularities or obstructions on the road or track over which the vehicle is passing; also to allow of a relative movement between the steering wheel or handle and the axle, so as to prevent shocks and vibrations in a vertical direction being transmitted to the steering-wheel or handle. There are ten figures. Fig. 2 is a part sectional front elevation. a , is the non-rotating axle which is of H-section. The steering wheels, b , b_1 , are carried each on a short spindle, c , which is pivoted to the brackets, d , d_1 carried by the axle, a . The spindles, c , are provided with steering arms, e , e_1 , which are connected together by the link, f . The steering rod, g , is pivoted at one end to one of the steering arms, while at the other end it is screwed to engage with the internal screw in the long sleeve-like boss, h , of the bevel pinion, j . This bevel pinion is supported in a swivelling-bracket, m . The pivoting-bracket is provided with two pivot pins in alignment with one another. The lower one, n , is pivoted directly in the bracket, o , which is carried by the axle, a . The

THE AUTOMOBILE IN THE MALAY STATES.—The use of the automobile is particularly appreciated in such countries as the Malay States. We have received the above interesting photograph from Mr. G. Dearie Russell, the Hon. Secretary of the Federated Malay States Automobile Club, who communicates with us from Kuala Lumpor, Selangor. We learn from him that there are no less than about 35 cars in constant use in Selangor where the roads are in very excellent condition and afford every facility for motoring. The owners and the cars in our picture are, reading from left to right, G. D. Lucas, 6-h.p. De Dion; Claude Severn, 16-h.p. Albion; Sir William Taylor, K.C.M.G., 8-h.p. De Dion; William Small, 8-h.p. Albion; A. K. E. Hampshire, 6-h.p. De Dion; Lee Kong Lam, 8-h.p. De Dion; W. E. Kenny, 6-h.p. De Dion; L. F. Brown, 5-h.p. Baby Peugeot; G. D. Russell, 10-h.p. De Dion; J. H. M. Robson, 10-h.p. Stevens Duryea.

THE AUTOMOTOR JOURNAL.

PASSING EVENTS.

"Folly . . . Controlling Skill."

IN 1903, the Commission on London Traffic commenced its labours, and in July, 1905, it issued its report. We commented at the time on the main features of this document, and drew attention to the very pessimistic attitude adopted by the Commissioners to the motor 'bus and its potentialities for dealing with London traffic, and to the extraordinary suggestion that the best way of dealing with the problem was the indefinite extension of the electric tram. After they had been at work for a year, the Royal Commissioners appointed, to assist them, three celebrated engineers, Sir John Wolfe Barry, Sir Benjamin Baker, and Mr. W. Barclay Parsons, and the report which these engineers put before, what a morning paper not inappropriately terms "the *inexpert* members of the Commission," has now been published. As was to be expected from technical men, the views put forward in this report are altogether different as regards the capabilities of the motor 'bus.

"If it be found," they say, "that these vehicles (motor omnibuses) can be economically worked and maintained at the speeds given, we think they will have an important bearing upon the transport of passengers in London, and may affect the consideration of railway and tramway policy."

and they add that

"the construction of tramways will not remove the congestion of the streets."

They bring hard figures to support this point of view.

The average speed of vehicular traffic during the crush and slack hours of the day has been taken, and these are the results :—

	Crush Hours.	Slack Hours.	Speed in Miles per Hour.
Motor omnibus ...	6½-8½	8½-11½	
Horse omnibus ...	3½-6	5½-8	
Electric tramway ...	5½-7	8½-11½	

From this it appears, therefore, that the motor 'bus is a vehicle which, without any previous disturbance or permanent alteration of the streets along which it runs, is able to deal with the traffic at almost precisely the same rate of speed during the slack hours, and at a very considerably better rate of speed during the more important crush hours than the electric tram. These views, it must be borne in mind, were come to some time ago, before the motor 'bus had given the satisfactory demonstration of its reliability and capacity for steadily dealing with the traffic of London streets, with which, during the past few months, we have all become satisfactorily familiar.

The situation possesses elements of humour. Here we have a body of gentlemen appointed by Government to enquire into and report on an important problem. After a year they find themselves unable to do without expert assistance, and they call in, very wisely, the best expert assistance they can obtain. And then when it comes to issuing their report, they pass over the views of their own technical advisers on one of the most important issues, and present a report which totally ignores the motor 'bus, and puts forward the electric tram as the one universal panacea for diminishing the chaos of our London streets. Unfortunately in this country, we are not unfamiliar with this sort of thing, and there is at any rate one great State department which is systematically accused of obtaining expert advice only to ignore it. Little good to the community is likely to result, when in this way "folly" is allowed to "control the skill."

Let Sauce for the Goose be Sauce for the Gander.

THE relative speed figures quoted above prove that the motor 'bus is a more efficient means of locomotion, and deals with the traffic of London more successfully than the electric tram is able to do, particularly during the "hours of most crowded life." This is, of course, what anybody gifted with common sense would have predicted, and is merely a further illustration of the disadvantage, even to the trams themselves, on which we have always insisted, of being confined to a definite track. And there is another aspect which the engineers seem to have omitted to mention. That is the much smaller extent to which motor 'buses delay other traffic than the electric tramcars do. To those who have been compelled to witness (with rage or cynical amusement according to temperament) the procession of sometimes as many as twenty trams closely jammed together in the neighbourhood of the Elephant and Castle on each line of tramway, and the ineffective attempts of all other traffic to get by them, will realise this to the full. But the chief conclusion to which these revelations in regard to the relative speeds of trams and motor 'buses point, is that our executive should insist on fair play. The motor 'bus is limited by law to a speed of twelve miles an hour, and this speed in point of fact it practically never exceeds, in spite of which handicap its average is better than the tram average. The tramcar is similarly limited by law to a speed of ten miles an hour, and whenever it has a free run it invariably

exceeds it, not by a trifle, but often by 100 per cent. That trams regularly and frequently run at speeds approaching twenty miles an hour was demonstrated by the amusing prosecutions instituted some time ago, in which, by the way, the magistrates imposed merely nominal penalties. Now the motor 'bus is a new and enterprising suitor for London traffic, and there is no doubt, as its present popularity shows, that its ultimate success would be hailed with satisfaction by every Londoner. It must be regarded as a very high testimonial to the general efficiency of the motor 'bus that it can maintain so high an average speed without ever having to indulge in excessive speeds to do so. Such a method of driving, too, must obviously be more beneficial to the upkeep of the vehicles.

The Royal Commission on Motor Traffic.

THE Royal Commission on Motor Traffic commenced its sittings on Monday last with Lord Selby in the chair, and all the other members duly in their places. The sitting was a formal one, and after considering the situation the Commission decided that they would not permit reports of the proceedings taking place before them to be published in the Press. On the whole we think that the decision the Commission have come to on this point is a wise one. No doubt their report, when presented, will be accompanied by an adequate *précis* or summary of the evidence put before them, and the public will then be able to judge the whole case on its merits without the confusion and false impressions which are likely to occur when persons not accustomed by training or education to take a judicial view of a situation, are presented piecemeal and in detail, with the pros and cons of an argument on which a good deal has been felt, and much more said and written. There has been much acrimonious feeling on the whole automobile question, excited in the opposing camps, and it would be for the benefit of nobody that the acrimony should be increased. This, however, would almost unavoidably happen should the evidence and arguments placed before the Commission be published from day to day as given. When the automobile arguments were being put forward the opponents of the movement would be furious, while when the members of the Highways Protection Association and their sympathisers were in the witness box, the feelings of automobilists would almost certainly be on edge. It is well, therefore, that the public knowledge of what is brought forward on either side should be delayed until both sides can be presented together.

A Hope Fulfilled.

WE last week ventured to express the hope that the Automobile Association would extend its beneficent activity to other districts beside the Portsmouth and Brighton roads, where it has already performed such excellent service. In fact, so well has it done its work on the Portsmouth road that we believe the police in that neighbourhood have been able to return to their ordinary duties of looking after property and preventing ordinary offences, with the result that Lord Onslow and others living in the district can cultivate their cabbages without fear or trembling. We are delighted, therefore, now to learn that the Association are extending their organisation of cyclists, scouts, and patrols to the Andover district. The result, we have no doubt, will be highly delectable to Colonel "Handover"

Harmer and his associates. They will to a large extent doubtless be relieved from what must be to them the disagreeable and distasteful duty of convicting such large numbers of gentlemen belonging to a class not usually accustomed to appear in police courts, and monotonously raking in large sums in fines for the relief of the local rates. In fact, we hope to see the operations of the Association so successful, that the "Hand-over" Bench will, at an early date, cease to be an exchequer paying-in office in relief of the local taxation, and will be able to devote its undivided attention to the gypsies, "drunks," casuals, and poachers, which previous to the advent of the automobile, formed the bulk of the clients of that august assemblage, and with which, from all that can be seen of their deliberations, they are specially, if not solely, fitted to deal.

♦ ♦ ♦

An Effect of the Motor 'Bus.

THE question as to whether the taximeter should or should not be introduced on the London cab has been discussed for quite a period of years, though they have been in use in Paris and in the principal towns of Germany for ten years or more. But, until recently, there has been no indication that the subject was ever likely to emerge from the stage of palaver into that of actuality. This, however, it at length really seems to be doing, and there can be little doubt that the change is due to the effect upon the cab trade of the motor 'bus. Along all the routes served by motor 'buses, it has been demonstrated satisfactorily that the motor 'bus is quicker than the cab, and the general recognition of this fact, added to the rivalry of the "tubes," is having a disastrous result for the cabman. At present, the men seem to be standing out against the introduction of the taximeter, but we believe in doing so they are standing in their own light. Possible customers are but too frequently prevented from hiring a cab by uncertainty as to what the real fare is, and the fear that they will be considerably overcharged or over "language'd." The taximeter removes all causes of dispute, and by doing so would certainly increase here, as it has done abroad, the number of the cabman's possible patrons. Under the competitive conditions which the motor 'bus has established, and is daily accentuating, it is essential for the horse cab industry, if it is to keep its head above water at all, to remove every cause which may by any possibility diminish its popularity. The best solution for the cabmen, however, is obviously to become motor cab drivers.

The Speed which a Car should Attain.

IN our present number we bring our articles on the Tourist Trophy question to a conclusion, including a table which we venture to hope will provide data of considerable interest to all owners of cars, and particularly to all who may desire to take part in, or to assist in organising, competitions on Tourist Trophy lines in the future. The table, which is the outcome of a large amount of calculation and practical experiment, will, together with the description and explanation which accompanies it, enable anyone to see at a glance (a) what speeds an average car with average load, and either a 13½, 18 or 22½-h.p. motor, can attain on any gradient of road of ordinary surface, either uphill or downhill; (b) the tremendous effect played by wind resistance in deter-

mining and limiting car speed—a point on which we believe that little concise data have hitherto been available; and (c) the great increase in fuel consumption which, as the result even of wind resistance alone, is occasioned by driving cars at high speed.

In addition to being of interest to the classes of readers we have indicated above, our figures will, we are sure, be found useful by the majority of car owners and drivers, for they provide in short compass significant information that is applicable in large measure to their own cars, and cannot but prove both instructive and useful to them. There are many consequences that will be found to emerge from the figures in the table. It would be impossible here to enumerate them all, but as an instance of their value, we may point out that any car owner who possesses an automobile of either of the three powers given, will be able, by the assistance of the table and by simply driving over a suitable stretch of good road, to ascertain whether the performance of the car is what it ought to be—and if he is driving it properly; the total weight of the car at the time should of course be that on which our figures are based, and its cross-section must be about that taken by us. A striking confirmation of the general correctness of our figures, and the *data* on which they are based, is afforded by their application to the Tourist Trophy Course in the Isle of Man, the result being that the speed shown to be attainable is almost exactly that which was in point of fact actually accomplished by the leading vehicles this year.

Petrol Engines for France to be built at Glasgow.

—An important agreement has been concluded between the Argyll Company, of Glasgow, and the Aster Company, of Paris, by which the former firm will in future build Aster engines, at their new works at Alexandria, for use in Argyll cars, and also for the Aster Company. In order to ensure that these engines shall be in every respect identical with the products of the French firm, the two companies concerned have arranged to obtain their materials from the same sources, and a staff of specially-selected French workmen are coming over from Paris to Alexandria to operate the new plant that is being laid down. Thus, though made in Scotland, the Aster-Argyll engine will be, down to the smallest detail, the same as the Aster, hitherto constructed exclusively in France. The agreement may be regarded as a fitting culmination of a long and mutually satisfactory business connection between the two firms. Even in the past, we learn that the French company have often been glad to adopt the many useful suggestions made by Mr. Govan—the managing director of Argyll Motors, Limited—for further improving the latest models.

The Argyll Company were amongst the first to recognise the merits of the Aster engine, and for a considerable time they have been one of the Aster Company's biggest customers. It is significant of the French firm's confidence in the new arrangement that they have placed with the Argyll Company an order for Alexandria-made engines for Paris. The Argyll Company and their predecessors, the Hozier Engineering Company, have used many hundreds of Aster engines, and the new arrangements will be a guarantee that their good qualities and distinguishing features will be fully maintained. It is also a decided triumph for British industry.

THE BRITISH ARMY AND MECHANICAL TRANSPORT.— PART III. *(Concluded from page 1267.)*

Military Lurries.

IN civilian life, the motor lorry is proving a great boon, but in the Army its advantages are less conspicuous, because it has another mechanical rival in the independent traction engine, and it has not, therefore, merely been required to supplant horse-traction at first-hand as it has done in civilian life. At home, for use in the neighbourhoods of permanent camps, where there is considerable transport work to be done by road, the motor lorry is in its element, and several of them are employed at Aldershot and elsewhere to great advantage. For field work, however, they suffer from an inherent disadvantage, viz., that the engine cannot be instantly disconnected from its load *en masse* for temporary purposes. The importance of this drawback may not be at

quantity of stores whose aggregate load is within the capacity of one engine may have to be delivered at several different places, and if those materials can be subdivided into separate wagons then an entire wagon can be left at its destination to be unloaded whilst the remainder of the train proceeds to the next station.

Present Developments.

At the present day the comparatively small traction engine is receiving greater favour than the very heavy machine, and the reasons why this should be so are not far to seek. The demands of transport are naturally of a very variable character, and it is impossible to ensure that the bigger machines shall always be used under reasonably efficient conditions, as the following incident

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—The breakdown gang which form an independent section of the repair train. In the wagon, on the extreme left, are lifting-jacks, fair-leads, and other small tackle useful in breakdown repair work. A large portable gin is visible in the centre of the photograph, and the traction engine is fitted with a powerful gib crane and a winding drum. The method of anchoring the capstan, shown in the foreground, is interesting, the pull being taken in any direction by a systematic arrangement of fair-leads also anchored to the ground in suitable positions.

first sight apparent, for it has to do with a difficulty—not previously mentioned—which is frequently met with in military transport. It may happen that a transport train gets stuck in particularly unsuitable ground, where the engine is powerless to move its load. Any separate tractor can be easily uncoupled from the train, and the chances are that it will be able to extricate itself from the difficulty, and to assume a position on firm ground, where it will be able to haul up each unit of the train by the aid of its winding drum. If a self-propelled lorry gets into a similar plight there is no alternative but to unload, which is not only a lengthy process by itself but of little advantage to the situation when accomplished; for although the lightened machine may, and in all probability will, get free, there is no means of re-loading except by carrying the stores piecemeal after the lorry. There is another point, too, in connection with dividing the load from the engine which is very important. A

in the South African war will show. It happened to be necessary to transport a load of 5 tons to a certain place without a moment's delay. The only traction engine available weighed 20 tons, and was capable of dragging, under suitable conditions, a useful load of 40 tons. At the time there was nothing else which required to be despatched in that direction, so the 20-ton engine, with its full complement of men, was sent out with its 5-ton load. This it safely delivered at the other end, and then it happened to fall into a ditch, and another engine had to be requisitioned to get it out. This incident throws considerable light on the question of army transport, because it forms such an admirable illustration of at least two very important phases. One of them, viz., the inefficient use of such large engines, has already been mentioned, the other is the lesson which it teaches as to the undesirability of allowing any transport engine to go out alone lest it should get into a difficulty from which

soon turned their serious attention to the requirements of the War Office Committee is in itself sufficient evidence of how important this branch of automobile construction may become to the industry.

Experience will show in what other particulars the internal combustion engine is superior to the steam engine, but it is, of course, in the greatly increased range of action which this type of tractor affords that its importance, from a military point of view, is at present centred.

When such an engine reaches a thoroughly satisfactory state—as there is every reason to hope it will do in the near future—then, in all probability, a new era will begin in the annals of Military Mechanical Transport.

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—One of the workshops belonging to the first section of the repair train. The apparatus in the centre of the wagon is an "H.F." vulcaniser for the repair of the pneumatic tyres used on the officers' motor cars.

NOTE.—For the more important references to Military Mechanical Transport, and the heavy oil engines specially constructed for the purpose, see *THE AUTOMOTOR JOURNAL*, Vol. VIII., pp. 1108, 1334; Vol. IX., pp. 36, 853, 863; Vol. X., pp. 384, 448, 507.

it cannot extricate itself without the aid of another machine. Lightness, therefore, is apparently a most desirable feature in each unit of a transport train, and if what weight there is can be made not only useful in that it represents stores, but useful also for the purposes of transport, so much the better for efficiency of the train.

These and other questions relating to the development of mechanical transport are in the hands of a War Office Committee, which is presided over by Col. Clayton, and of which the Secretary is Major Lindsay Lloyd. The energies of this Committee, which has already done such good work, are at the present moment mainly centred in obtaining a thoroughly suitable internal combustion engine. This engine, needless to say, must use kerosene, and not petrol, as its fuel. Already Messrs. Thornycroft and the Wolseley Company have engines of their own—of which descriptions have appeared in these columns—under official trial at Aldershot, and the mere fact that two such firms of repute should have so

THE BRITISH ARMY AND MECHANICAL TRANSPORT.—The Machine Shop of the Repair Train. This wagon contains a large lathe and a milling machine, which are, like all the other machine tools in the train, electrically driven.

The Smoke Consuming Puzzle.—It is satisfactory to note that common sense is beginning to make itself more and more felt in magisterial decisions on motor car questions. At any rate this is so with regard to stipendiary magistrates, who, needless to say, are as a rule less prejudiced, and take a more judicial view of cases put before them than is customary with the "great unpaid." An example in point is provided by a case tried recently before Mr. Plowden at Marylebone Police Court, where the London Road Car Company was summoned at the instance of the County Council for, it was alleged, running one of their motor 'buses which did not as far as possible consume its own smoke. It was stated when the case was brought on that on precisely similar evidence to that which would now be tendered, Mr. Denman, the "Rhodamanthus of Marl-

borough Street," and Mr. Lane, of West London, had respectively convicted and acquitted. Mr. Plowden smilingly observed that this put him in a difficulty, as in that case it would be impossible for him to agree with both of the learned magistrates, and evidently feeling himself thus free to take a common-sense view of the situation, he "found that the fumes complained of were fugitive and temporary, and therefore came within the exemption clause." He accordingly dismissed the summons, giving two guineas costs, this award of costs being not the least significant point in Mr. Denman's action.

The motor lurry has at last entered into the Yarmouth herring industry, and a petrol lurry, capable of carrying 1½ tons, is now in service in that town for carting fish.

THE 1905 ARGYLL CARS.—PART II.

(Continued from page 1260.)

IN our last issue, we gave some important information concerning the great progress recently made by the manufacturers of these very successful cars. The special features of the standard models were also mentioned, and we briefly enumerated the various types that are now being supplied. We now proceed to deal with the details of construction.

Side view of the 16-20-h.p. Argyll Car, fitted with the standard side-entrance body.

The Main Frame.

The side members, unlike those of most pressed-steel frames, have a cross-section resembling an inverted U, but it is a "U" having practically square—rather than rounded—corners. They are thus particularly well adapted to resist the strains that are imposed upon them in practice, and they also have many advantages from a constructional point of view. Tapering off back and front, from the centre, the greatest depth is where it is most required, and it is only necessary to curve the projecting ends downward in order to make them form the brackets for the side springs. Side members of this shape give to the frame, moreover, a very neat external appearance when the car is completed. In front, the cross-member is given a suitable bent shape to pass beneath the radiator, thus allowing a radiator of large size to be used, and all Argyll frames have at least one substantial intermediate cross-member, which lies just behind the clutch, and supports its "driven" shaft; in Fig. 1, which represents the 24-h.p. chassis, is seen a second intermediate cross-member just behind

the gear-box. Between the radiator and the frame, felt packing is introduced to form a soft cushion. In all cases, the engine and the gear-box are fixed direct to the side members, and consequently no under-frame is needed.

As usual, semi-elliptic side springs of considerable length afford the necessary suspension for the frame; those at the rear, which lie outside, have shackles at both ends. At each side there are radius rods to tie the back-axle to the frame, these rods relieving the springs of the torsional strains that are set up in all axle-casings both by the "drive" and by the brakes.

The Front Axle.

In Fig. 3 as well as in Fig. 4, the front axle is well illustrated. In both these figures the stay, A, and the very substantial steering-head brackets, A', are prominent. They render the tubular axle extremely strong to resist road-shocks, which is a very important consideration on any car—particularly when it is necessary (for other reasons) to employ a curved axle. It may also be pointed out, incidentally, that the stayed axle adds

Fig. 3.—Front view of an Argyll Car, showing the distinctive appearance that is characteristic of all Argyll vehicles. The tie-rod that stiffens the tubular axle, the substantial steering heads, and the large honeycomb radiator—behind which is fitted a belt-driven fan—stand out prominently in this illustration.

Fig. 4—In this sectional drawing, the construction of the stayed, tubular front-axle, and of the steering-heads, employed on Argyll Cars, is shown in detail. The staggered arrangement of the spokes in the road-wheel is also indicated, and the design of the dust-proof ball-bearing is rendered clear.

to the distinctive appearance of the Argyll car, when seen from the front as in Fig. 3.

In Fig. 4, the steering-head and the stub-axle, carrying the road-wheel, are shown in section, and an opportunity is thus afforded for appreciating other good "Argyll" features. The wheel itself revolves on ball-bearings of the D.W.M. type (with separating springs between the balls), which are made with ample space around the shaft for grease, and with an anti-friction thrust collar, A², that also excludes dust. Absence of undue wear in the steering-heads is ensured by providing them with ample bearing surfaces of very hard material, and by an effective system of lubrication. The fixed steel pin, A³, is rigidly secured to the bracket, A¹, by a locked nut beneath, this nut tightening up the conical faces at the upper end of the pin, A³, at the same time that it forces the split conical sleeve in around the lower end of the pin. The pin itself has a grease-cup above, and is drilled out with oil-ways that lead to the ball thrust-bearing, A⁴, and to the hardened steel

Fig. 6.—Sectional drawing, showing the internal construction of the Argyll steering-gear, and the steering-pillar with its wheel. The timing-lever (C¹) and the throttle-lever (C²), together with the stationary quadrant (C³), with which they engage, are also indicated in this illustration.

bushes that constitute the plain bearings for the swivel, lower down. The ball bearing, which takes the weight of the car, has a dust-collar encircling it.

The Steering-Gear.

Strong, simple, and adjustable for taking up any wear, the steering-gear is of that type in which a coarse-pitch

Fig. 5.—Two views of the Argyll steering-gear. On the left it is shown intact, with the lever-arm (B¹) that is connected to the steering-heads in place. On the right, the oil-tight casing that contains the gear mechanism is taken apart, and the triple-threaded worm (B¹) with its nut (B²) are exposed to view.

Fig. 7.—View from above of the Argyll steering-wheel, fitted with the timing (C¹) and throttle (C²) levers, by which the driver is enabled to control the power and speed of the engine. These conveniently placed hand-levers automatically lock themselves to the toothed quadrant (C³), whatever position they may be made to assume.

Fig. 8.—This illustration shows some of the extremely neat and convenient little ball-and-socket joints that are employed by the Argyll Company for connecting the control-levers with the timing-gear and with the throttle-valve.

screw and a nut are employed instead of a worm-wheel and a toothed segment. It is shown, both complete and in parts—by photographs—in Fig. 5, while Fig. 6 is a sectional drawing that renders clear the entire construction.

The central shaft, B—to which the steering-wheel is rigidly fixed—has the triple-threaded screw, B¹, formed near its lower end, and around this screw rides the travelling nut, B². The “nut” is made in two parts to allow any back-lash that may develop to be taken up at any time, and it is made to engage with the forked lever-arm, B³, as seen in our illustrations. The forked arm, B³, is solid with the fulcrum-pin, B⁴, and it is to the projecting end of the fulcrum-pin, B⁴, that the lever, B⁵, is secured.

Grease is retained in the casing enclosing the entire mechanism, and there are screw-plugs top and bottom of this casing for putting it in, and draining it out. The two halves of the casing are divided in such a way that the bearings for the fulcrum-pin, B⁴, are formed between them.

The base of the main shaft, B¹—which is hollow, and contains three concentric sleeves—is carried by an adjustable thrust-collar, that enables all end play to be taken up, and the necessary lock-nuts are provided for

holding it in place. Inside the shaft, B¹, the innermost sleeve, C, connects the “timing” lever, C¹, (above the wheel) with the lever-arm, C² (beneath the steering-gear casing), and similarly the sleeve immediately surrounding the sleeve, C, connects the throttle lever, C³, with the lever-arm, C⁴. The third sleeve (inside the shaft, B¹) carries the toothed quadrant, C⁵, for the levers, C¹ and C³, and thus holds the quadrant stationary even when the steering-wheel is being operated. At the top of the innermost sleeve, C, is an oil plug, through which all three sleeves can be lubricated.

The “Timing” and “Throttle” Levers.

Fig. 7 demonstrates the particularly neat and effective manner in which the small hand-levers, C¹ and C³, are arranged above the steering-wheel. They are normally locked in whatever position they may have been placed, for they have spring catches that engage with the teeth of the quadrant, C⁵. To disengage them, it is only necessary to pull the small handle outwardly, and they can then be moved over the quadrant freely.

One of the neatest features of these Argyll cars is that small ball and socket joints are used on the rods that constitute the control mechanism for the engine. The joints themselves are quite simple, and are remarkably effective, for they give the same facility of getting round awkward corners that do “Bowden” wires, and yet they have no corresponding drawbacks. Some of the joints, with their rods, are shown in Fig. 8, in which two ball-ended bell crank-levers, placed at a sharp angle, are seen connected together by a straight rod; in the same illustration is a sample rod with socket joints at each end, and a sample ball-ended lever-arm. The sockets, C⁶, which are adapted to be screwed over the ends of the rods, are split to enable them to spring into place, over the ball, C⁷, and they are provided with a locking screw, C⁸, that

Figs. 9 and 10.—The rear portion of an Argyll Chassis, with road-wheel removed, showing the live axle and the manner in which it is connected with the frame. In both illustrations, the internal expanding member of the hub-brake is exposed to view, but in Fig. 9 the toggle-mechanism is in its “on” position, and the detachable dust-cover (G¹) is in place, whereas in Fig. 10, the toggle-mechanism is in its “off” position, and the dust-cover has been removed. The dust-cover (G²), which is made in two parts for the purpose, enables the brake-mechanism to be adjusted without taking off the road-wheel.

The "Live" Rear Axle.

This extremely important part of any "chainless" car is well shown in Figs. 9, 10, and 12, and is also clearly visible, from another point of view, in Fig. 1. In Fig. 12 are seen all the various parts dismantled. The stationary portion, which is rendered free from "spring" by stay-rods, D^3 , fitted above and beneath, consists of a strong casing, D , containing the differential gear, E , of steel tubes, D^1 , enclosing the two halves of the revolving shaft, E^1 , and of the brackets, D^2 , that carry the brake mechanism as well as the springs. The casing, D , is made in two parts, and is fixed to the steel tubes, D^1 , in such a way that the upper part can at any time be taken off for examining the gearing without having to remove the entire axle from place. Complete examination is thus rendered quite easy. The upper half of the casing also has an inspection cover that gives sufficient access for filling up with lubricant, and for making any ordinary cursory examinations.

The axle shafts, E^1 , which are made of nickel steel, and carry the road-wheel hubs, E^3 , on their projecting ends, are mounted on four roller bearings, E^4 , and are driven by the bevel-wheel, E^2 , through the differential-gear, E . On each side of the differential, ball-bearings, E^5 , are fitted, in order to take the end thrust of the bevel-wheel; these are arranged in Fig. 12—as are the sleeves for the roller-bearings—near the positions which they occupy when in place. The roller-bearings, which are made in the Argyll factory, are of that type in which a cage is used to keep the rollers in position.

An important feature of the bevel gearing is that the bevel-pinion, F —which meshes with the bevel-wheel, E^2 ,—is supported by hardened steel bushes on both sides,

Fig. 11.—View of an Argyll road-wheel, showing the staggered arrangement of the spokes which adds considerably to its lateral strength. The spokes are also so shaped inside the hub, that the entire wheel can readily be tightened up, should the wood shrink after construction.

prevents them from slipping off again. The many advantages of this device cannot fail to appeal to all motorists.

Fig. 12.—The Argyll live-rear-axle, dismantled to show its internal construction. The detachable casting that enables the bevel-wheels (F and E^2) and the differential (E) to be examined readily at any time, and the differential planet-wheels with the driven bevel-wheel (E^2) are seen above the main portion of the stationary casing; the hubs of the road-wheels, with their brake-drums lie at each end of the main casing; and, beneath these parts, are placed the axle-shafts (E^1), with their roller-bearings and ball-thrusts.

instead of being allowed to overhang inside the casing, D. It has, moreover, a ball-thrust-bearing behind it. The shaft, F¹, to which it is fixed, is given a square cross-section outside the casing, where the propeller-shaft is coupled up to the usual universal-joint, as seen in Figs. 9 and 10.

Turning to Figs. 9 and 10, the flat radius-rods, D⁴, will be noticed; they pass from the spring-brackets, D³, on the axle to those carrying the front shackles for the springs.

The Hub Brakes.

Also clearly visible in Figs. 9 and 10, are the internal, expanding brakes that act direct on the hubs of the driving wheels. The mechanism by which they are operated, and are compensated to ensure an equal pull on both brakes, is shown in Fig. 1. The hand lever, G, at the side of the car is fixed to the transverse rock-shaft, G¹, and this shaft carries fulcrum-pins for the two bell-crank-levers, G². It is to the bell-crank-levers, G², that the brake rods, G⁴, are attached, and since the two bell-crank-levers are connected together by the rod, G³, it follows that the tension on the rods, G⁴, must equalise itself immediately the shaft, G¹, is rocked about its axis to apply the brakes.

In Fig. 9, the road-wheel and its brake-drum have been removed to expose the expanding brake-member to view, and in this illustration the toggle-mechanism, G⁵, is in its "on" position. In Fig. 10, however, two points of difference will be noticed, for, on the one hand, the toggle-mechanism, G⁵, is in its "off" position, and, on the other hand, the dust-proof cover, G⁶, has been removed. By comparing the two views, the action of the brake-mechanism will therefore be readily understood; the lever-arm, which is controlled by the rod, G⁴ (Fig. 1), is fixed to the pin, G⁷; this, in turn, is connected with the toggle-mechanism, G⁵; and the toggles tend to force asunder the two brake-shoes, G⁸, both of which are pivoted at G⁹.

An extremely useful point about these hub-brakes is that they can easily be inspected or adjusted, and that it is not necessary even to remove the road-wheel—or to

"jack up" the car—in order to do so. The cover, G⁶, renders this possible, for it is made in two parts and can, therefore, be taken off without difficulty. Every necessary provision is made for keeping the brakes properly adjusted at all times, and it is only at very infrequent intervals of time that the adjustment in the toggle-mechanism itself need be altered. The shoes are made of phosphor-bronze, and their effect on the brake-drum is equally powerful whether the car is moving forwards or backwards.

The Road Wheels.

Two advantages are obtained by the construction adopted in the Argyll road-wheels, for the spokes are not only staggered—that is to say, alternate spokes slope inwardly and outwardly from the felloe to the hub—but they are mitred in opposite directions where they fit up against one another to form the hub. The staggered arrangement, which is visible in Fig. 11, renders the wheel very strong laterally, thus reducing any chances of its collapsing when a car is travelling at a high speed round a corner, or has skidded up against the kerb. The two devices together enable the spokes to be tightened up, should they get slack owing to a shrinkage of the wood, for it is only necessary to reduce the thickness of fibre packing-pieces which are introduced between the wedge faces of each spoke and the hub-flanges, and the two flanges can be drawn together by the bolts. By this operation, the inner ends of the spokes are forced up closer to one another, thus rendering the hub more solid, and, simultaneously, all the spokes are pushed outwards so that they are tightened up into the felloe. This construction is more especially important for hot climates than for this country, good as it is in any case.

The wheels employed on the standard Argyll cars vary in size from 36 ins. to 32 ins., there being intermediate 34½ in. and 34 in. patterns for the 24-h.p. and 16-20-h.p. models. Similarly, the tyres with which they are shod are either 920 by 120 mm. (26-30-h.p.), 880 by 120 mm. (24-h.p.), 875 by 105 mm. (16-20-h.p.), or 810 by 90 mm. (10-12-h.p. and 12-14-h.p.).

(To be continued.)

Royal Commission on the Motor Car Acts—The Commission sat for the first time on Monday last, when the proceedings were, on the whole, of a purely formal nature. The Commission, however, decided that the Press would not be admitted to the sittings. At the second sitting on Tuesday the taking of evidence was commenced, when the witnesses examined were Mr. G. E. Wainwright, principal clerk at the Local Government Board and chief of the department administering the Motor Car Acts; the Hon. Arthur Stanley, M.P., Chairman of the Automobile Club and of the Motor Union of Great Britain and Ireland, and Mr. Rees Jeffreys, Secretary of the Motor Union and head of the Legal Department of the Automobile Club, whose examination was continued on Wednesday.

New Heavy Vehicle Regulations.—Mr. W. Worby Beaumont has written to the Automobile Club, suggesting that the Local Government Board should be asked to make an addendum to the present regulations affecting heavy vehicles, containing a clause specially referring to the steering-wheels of motor wagons. No specific reference being contained in the existing regulations, the L.C.C. officers are construing them to mean that the

minimum width of 5 in., which applies to the driving-wheels, must also be enforced for the steering-wheels, although the steering-wheels may actually be carrying less weight than is carried by a trailer, the minimum width of tyres for which is specified as 3 in.

THE EMPIRE SPRING WHEEL.

(Concluded from page 1264.)

THE tyre, G, is mounted on a rim, G', in the usual way, and the connection between this outer member of the wheel and the inner member already described is in the first place effected by a set of trolleys, D, and driving-plates, C, and in the second place—for the sole purpose of aligning the two members, B² and G', and taking all side thrust—by guide-plate, H.

The trolleys, D, which are fitted with two rollers, D¹, are pivoted at C², to triangular plates, C, and these plates are themselves pivoted at C¹ to the star casting, B², and the anchor bolts, E³, respectively. The pins, C¹,

which secure the plates, C, to the casting, B², pass through the bosses, B⁴, situated only a little below the bosses, B³, carrying the rockers, F; and it will be noticed that these rockers are specially slotted in order to allow the pins, C¹, to pass through them without limiting their freedom of motion. The other pins, C³, which secure the plates, C, to the springs, E, are the same that form the hinged joint between the clamp, E¹, and the anchor bolt, E⁴. In Fig. 3, which is a photograph of an earlier type of wheel, the trolley will be noticed as being situated immediately over the centre of the springs, E, whereas in Fig. 4, they are shown in a different relative position, the result being that in this latest type the springs, now having a leverage over the trolleys, can be made somewhat lighter in consequence, and the points, C¹ and C³, are equally balanced on the trolley-pivot, C².

Owing to the normal eccentricity between the hub and the rim—which is due to the dead load of the car giving the

Fig. 5.—The "Empire" Wheel. Transverse Section.

springs a certain amount of initial deflection—only those trolleys which happen to be at any instant below the axle are actually in contact with the rim of the wheel. The others above the axle are prevented from touching the rim by the nuts, E⁴, coming up against the bosses, B³, on the central casting, B². The anchor bolt nuts, E⁴, for the lower springs, however, are, on the other hand, clear of their respective bosses, and any sudden shock which deflects the springs increases this clearance, and at the same time puts an additional stress upon the other anchor bolts which are holding down the upper springs.

If one of these upper bolts were to break, the effect would be equivalent to the puncture of a pneumatic tyre, for the whole system would collapse; in practice this would

Fig. 6.—The "Empire" Wheel. Detailed drawing showing a portion of the wheel on a large scale, in order to illustrate the method of supporting the springs, and the shape of the inclined track for the trolleys which introduces the spring drive element.

not entirely disable the wheel, however, because the presence of the reserve springs, E², would enable the wheel to continue running, and would even supply an element of resiliency.

The Spring Drive.

Almost as important as the resiliency of the wheel itself is the resiliency of the transmission from the

Fig. 7.—The "Empire" Wheel. View of the interior, after removing the central member, showing the guide plate, H, which takes all side shocks.

Fig. 8.—The "Empire" Wheel. Elevation (part sectional), and cross-section of the model specially designed for heavy vehicles.

engine. The heavier the vehicle the more important is it to damp out any fierceness in the clutch and, by preventing inequalities in the road from having an undue effect, to maintain the load on the engine as even as possible. In the "Empire" wheel a spring-drive has been introduced in a very simple and ingenious manner, without either employing additional springs or stressing those which are already in use in an unsuitable manner. To effect this the inner face of the rim of the wheel is cast with projections, G^2 , and, when the inner member of the wheel is put in place, the trolleys are so arranged that they straddle these projections which then form inclined tracks for the trolley wheels which lie on either side of them. The

result is that no sooner does the engine begin to drive the inner member than this member rocks round until the trolleys have mounted a certain distance up the incline, G^2 ; in doing this they have, of course, been compressing the springs, E, and before they have gone very far the resistance of the springs stops their further motion, and the wheel begins to rotate *en masse* in the usual way. The actual relative rotary motion between the two members of the wheel is, of course, very small, but the value of the spring-drive is none the less considerable, because the gear ratio between engine and road-wheels very greatly magnifies its effect.

Mention has already been made of the guide-plate, H, which takes all the lateral strain. This plate is cut from a sheet of steel about an eighth of an inch thick, and is star-shaped, as shown in Fig. 7. At its centre it is bolted to the hub member, B, and its three arms are held in guides, G^3 , which are rivetted to the back cover, G^4 , of the wheel. The back cover,

Fig. 9.—The "Empire" Wheel. Detailed drawing showing the arrangement of the reserve springs on the "heavy type" of wheel.

Fig. 10.—The Empire Wheel. Two views of the "heavy-type" wheel which has been specially designed for commercial vehicles. The view on the left shows the wheel complete, but three of the little cover plates, D^2 , have been removed to show the guides for the trolleys, D. On the right, the wheel is shown with the cover removed so as to expose the interior. Although of the heavy vehicle type, the wheel from which these photographs were taken has been constructed for use on a Cadillac touring car.

Fig. 11.—The "Empire" Wheel. Modified form of the "heavy type" wheel, in which the track for the rollers is on the inside of the rim.

G⁴, is itself securely riveted to the rim so that, with the guide-plate in place, the wheel as a whole is strong enough to withstand any side shocks to which it is likely to be subjected. In order not to impede the relative motion of the inner and outer members of the wheel it has been necessary to enable the guide-plate to move also, and this, it will be noticed from the illustration, has been provided for by the ample clearance between the edges of the plate and the ends of the guides. On the front of the wheel is another cover-plate, G³, fitted with a hub cap, G¹⁰, and when these are in place a third of the interior of the wheel is filled with oil. A pad-ring, G⁸, is fitted to make the wheel quite oil-tight and a mud-guard, G⁷, is also provided to prevent dirt from splashing on to the rubbing surface of the pad.

Wheels for Heavy Vehicles.

The type of wheel which Mr. Robinson has designed for heavy vehicles is shown in Fig. 8, in principle it is identical with that already described, although its component parts are somewhat differently arranged. It might almost be said that the touring wheel already described has been turned inside out in order to produce this heavy type of wheel, for it will be noticed that instead of the trolley wheels, D¹, running on the rim they now run on the central casting, and while the rockers, F, were previously pivoted on the central member they are now pivoted on the rim. The central casting, B², which is naturally made as light as possible, is mounted directly on the axle, the flanged housing, B, being dispensed with, although the sleeve, A², is retained. The central casting, B², has no longer the same pronounced

star-shaped appearance that it had in the other model, its contour being now of a more sinuous character, in order to make a suitable inclined track for the trolley wheels, D¹. The springs, E, are, in this type of wheel, carried directly by the trolleys, D, while the rockers, F, are pivoted on pins, F², which pass through lugs on the steel rim.

As the trolleys have to transmit the drive to the outer member, their trunnion-ends, fitted with square blocks, are mounted in guides, C, cut in the sides of the wheel, small covers, D², being provided to enable the blocks to be passed into place and retained there. Side shocks are taken in this wheel by making the side plates, H, overlap the central member on either side, distance bolts, H¹, being provided at intervals to stiffen the sides and guard against possible distortion through shock. No reserve springs are fitted to the wheel illustrated in Fig. 8, but the manner in which they would be introduced when necessary is shown in Fig. 9, which represents a small portion of another wheel of the same type.

It only needs a glance at the illustrations to show that such a wheel as we have described must have needed very careful thought and design. It is essentially an "engineer's job" from beginning to end, and although somewhat complicated in appearance, perhaps, it is in reality very simple, and many of the early difficulties of construction have been overcome by the use of castings instead of sheet steel. Of the two types, that specially designed for heavy vehicles has the more simple appearance and the fewer parts—which is, perhaps, an advantage, for it is, we are of the opinion, in connection with commercial work that spring wheels will find their greatest scope for useful employment.

THE notorious Knaresborough Bench, which is now running Andover very close in regard to the "justice" of its proceedings, was the scene of a rather amusing motor car case at the last session day, in which Lieut. Christopher Leather, of The Friary, near Sheffield, was summoned for exceeding the speed limit. Lieut. Leather's solicitor made a gallant fight for him, and he even tried to get on the fair side of the Bench by saying that they were all what they called sportsmen, and he believed from the appearance of the Bench that they were also. Needless to say, this observation was hailed with laughter in court. And though the police evidence was of the usual kind, the Bench fined the defendant £7 and costs. Mr. Wilson, the solicitor for Lieut. Leather, gave notice of appeal. Solicitors practising before this Bench in future will probably avoid the mistake of suggesting either that its members are sportsmen or even look so.

WE referred last week editorially to the proposal to build roads exclusively for motor traffic, to the impolitic character of the scheme, and to the conclusions which we knew would be drawn from it, and even last week we were able to bring forward at least one instance of how the effect on the anti-automobile Press was beginning to become apparent. Now we have the egregious Highways Protection League, which might be better termed a league for monopolising the roads for the horse, straying cattle, and irresponsible pedestrians, putting forward their opinion that—

"The real solution of the traffic problem, in the opinion of the League, lies in those who wish to travel at high speed doing so on roads set apart for the purpose. Perhaps it may be found practicable also to add a smaller way on each side of these roads reserved for bicycles."

and then no doubt the League would argue that automobiles should be kept off ordinary roads altogether!

THE MORSE CHAIN.

THERE is very little in the mere appearance of the Morse chain which would strike the casual observer as peculiar, more especially as the "silent" chains manufactured by Messrs. Renold have now become so familiar. In detail, however, it is entirely different to its prototype, and its construction is also extremely interesting.

The Morse chain—of which we give two illustrations—originates from America, but the Westinghouse Brake Company hold the exclusive rights of British manufac-

pin, B', is "set" in such a way that when the chain is nearly straight the pins have two flat faces in contact instead of only a "knife edge" and a flat face as is the case when the chain is bent.

In this way, the pins in the portion of the chain between the wheels are afforded a very considerable bearing surface at the time when they are doing most work. A consequence of this is that the chain has a very limited flexibility in one direction, because the pins form a stop, which prevents anything but a very slight inward "sag" to occur on the top side of the chain.

Owing to the elimination of rubbing friction, lubrication is considered by the manufacturers to be superfluous. Dirt is, of course, liable to find its way into the joints, and the lower edge of the pin, B', has been chamfered off in order to allow the dirt to accumulate in a position where it will not interfere with the working surfaces, or to eject it.

The normal drive is always transmitted from the wheel on to the face, C, of each link, whence it is taken through the two pins on to the link behind it. At first sight it appears as if the links were being *pushed*, but this is due to the curious construction which causes each link to receive the load from the tooth of the link in front of it instead of directly through its own tooth. It will be noticed, too, that the plates forming the links are only provided with proper "teeth" on one end, and as there is, therefore, only one driving face, C, on each link, the chain is normally what might be called "single acting." This does not prevent the chain from being used for temporary reversing purposes, but when it is required for transmitting power equally in either direction a slight modification is made in the standard design in order to provide the necessary driving face on both ends of each link. Even then, however, the

link is not formed with two complete teeth, but the small end is enlarged somewhat in order to give sufficient driving face to enable the pressure to be transmitted correctly through the pins. It is, it should be mentioned, due to

Fig. 1.—The Morse Chain.—View showing the chain fitted in place on a pair of wheels. It is retained in place by central plates in the chain which engage in a groove cut in each wheel.

ture. It is constructed on an entirely new principle, which eliminates the rubbing friction between the links and their pins, and a consequent efficiency is obtained which, we are informed, approximates to the exceptionally high figure of 99 per cent.

The principal peculiarity of its construction consists in the use of two specially shaped pins in each pin-hole. Each of these pins is fixed to its own composite link, so that the pins rock against one another instead of the links rocking about the pin, as is the case in an ordinary chain. The details of this arrangement are very clearly illustrated in Fig. 2, which shows a short length of the chain in which one of the riveted heads has been cut away to expose the pins. Each complete "link" of the chain is formed by a set of thin plates, the number of which is, of course, determined by the width of the chain. The ends of the plates of adjacent links interlace so that their pin-holes coincide, and when the two pins, A' and B' (Fig. 2), are driven into place, the pin, A', becomes rigid with the link, A, while the pin, B', is fixed to the link, B. The pin, A', has a semi-circular section, while the section of the pin, B', approximates to a sector. The flat face of the pin, A', thus forms a fulcrum for the pin, B', to rock upon. It will be noticed on close examination of Fig. 2, that the

Fig. 2.—The Morse Chain.—View showing the construction of the chain and the method of joining the links by means of two pins, A' and B', which rock about one another and so eliminate rubbing friction at the joints.

the links never being made with two full teeth that it is possible to use very small sprockets with these chains.

The chain is retained in place on the wheels by means of the plates, D, which are fitted down the centre of the chain. These plates are accommodated in a groove, which is cut in the wheels, and in this way the chain is prevented, by the teeth of the wheels, from sliding off sideways.

LONDON TRAFFIC PROBLEM. THE ENGINEERS' REPORT TO THE ROYAL COMMISSION.

IT was in July of this year that the first of the eight volumes of the Blue Book dealing with the report of the Royal Commission on London Traffic—which commenced its labours in February, 1903—was issued. The seventh volume has only just been published, and the eighth has yet to appear. These last two volumes are the bed-rock out of which the Commission's Report was hewn, for they contain the facts, figures, and suggestions of the engineers who formed their advisory board. As the eighth volume will only contain the plans and drawings illustrating certain of the more important proposals, it interferes but little with a full comprehension of the Report as regards details, and not at all with the understanding of the general lines on which the engineers proposed that the problem of London traffic should be solved.

There can be little question that this particular Blue Book forms the most valuable contribution to the subject of London traffic which has so far been compiled. The names of the three engineers concerned—Sir John Wolfe Barry, Sir Benjamin Baker, and Mr. W. Barclay Parsons, engineer to the New York Rapid Transit Railroad Commissioners—are an all-sufficient guarantee of ability, while the Report itself bears the hall-mark of thoroughness in every respect.

At the time when the first volume of the Blue Book—containing the Report of the Commission—was issued, we were constrained to draw attention to its somewhat scant acknowledgment of the progress of the motor 'bus, but we are particularly pleased to now see what prominence these vehicles have been given in the advisory report which was submitted to the board by the engineers. It is all the more gratifying, too, when the extremely embryonic state of motor 'buses at the time when the Commission came into existence is remembered. In the carefully compiled summary, both the subsection on tramways and the subsection on railways contain the following clause:—

"The careful consideration of the probable future of the motor omnibus and its bearing on railway and tramway policy."

There can be no doubt that the motor 'bus loomed large among the probabilities of the future, as they appeared to the minds of the engineers, and the reason they make no definite suggestions directly connected with their use is admirably summed up in the following paragraph which appears in the aforementioned summary:—

"The time has not arrived for a definite judgment to be formed as to the practical and financial prospects of the motor omnibus in London, and of its true position in a system of rapid transit relatively to the electric tramcar. Whatever may be the eventual result, however, of the rival systems, the recommendations which we have made as to routes and similar matters, including the widening of streets, will remain unaltered."

Considered merely as a straightforward statement, this sentence is, at least, an emphasis on the afore-mentioned recommendations of the engineers that the Commission should keep the possibilities of the motor 'bus prominently before them. We would suggest, however, that there is also a clue in it as to the engineers' real opinion on the subject, for unless they considered that the motor 'bus had some element of probability in its future chances, they would hardly have taken the trouble to guard against the contingency of the Commission voting solid for it, and taking advantage of

the exceptional mobility of these vehicles to cover a possible curtailing of their suggestions as to the urgent necessity for widening streets and constructing main avenues. More especially is this likely to be so, as the quotation in question is preceded by the following, which speaks for itself:—

"Many of the views expressed would have to be modified considerably if a comparison has to be made between electric tramcars and motor omnibuses, the future of which is at present uncertain. . . . The tentative working in London of motor omnibuses within the past twelve months distinctly indicates that a rate of speed can be practically maintained by them which compares not unfavourably with the speed of electric tramway cars in similar thoroughfares."

For those to whom the question of London traffic is a business matter, the engineers' report should be invaluable, but it is far too long and conscientious in detail, from the motorist's point of view, for us to give our readers the benefit of further extracts. There are, however, a few facts and figures contained in it which cannot fail to interest, because of the light which they throw on the enormous dimensions of the field open to the application of the commercial motor vehicle for public service work alone.

"Greater London"—which is the name given to the whole district included in the Commission's Report—extends for about 15 miles around Charing Cross, and has an area of 116 square miles. In this vast field there are some 3,000,000 working inhabitants, of whom about 400,000 have to make a daily journey in order to get to their places of business. In all, however, of the nearly 1,200,000 people who enter and leave the City daily, only about 272,000 are carried by railways. In the "central area," tube railways are used by about 380,000 people during the day, and some 520,000 make journeys wholly or partly by tram, while no less than 1,150,000 use omnibuses. In greater London 1,164,000,000 passenger journeys are made in a year, 301,000,000 by railways, 405,000,000 by tramways, and 458,000,000 by omnibuses.

The railway and tramway companies expend on an average about £5,000,000 per annum on the accommodation of London traffic, and there are now in Greater London 630 miles of railway and 203 miles of tramway in operation. In addition to this, however, there are 147 miles of tramway authorised but not yet built. About 110 miles of the existing tramway are working electrically. The following are the relative speeds officially given of the three systems of passenger traffic at present in use on our roads:—

	Crush Hours.	Slack Hours.	Speed in miles per hour.
Motor omnibus ...	6½—8½	8½—11½	
Horse omnibus ...	3½—6	5½—8	
Electric tramway ...	5½—7	8½—11½	

The new streets advised by the engineers range in width from 24 ft. to 94 ft. roadway, and they are divided into five classes, of which the widest is styled "Main Avenues."

WHEN Mr. G. W. Davey, of Lytton Court, near Hereford, was driving his motor car near that town recently, he stopped to allow some horses under the conduct of a certain William Powell, of Hereford, to pass by. This, however, did not satisfy the requirements of William Powell, who struck Mr. Davey over the face with a stick, inflicting a considerable wound upon him. For this he has very properly been sent by the Gloucester magistrates to prison for six months.

RACES, RECORDS, AND TRIALS.

VANDERBILT CUP RACE.—Hemery, who last Saturday, won the Vanderbilt Cup Race for France, on his Darracq Car.

Vanderbilt Cup Race.—After a keenly-fought battle on Saturday last, Hemery, the well-known driver for the Darracq firm, succeeded in securing this trophy in the race over the Long Island course in America. His time for the full distance of 283 miles was 4h. 36m. 8s. The cup is thus won by France, who, however, through the A.C. de France, had previously, as announced by us, decided not to compete in next year's race. The Cup will, therefore, remain in America, by this determination of France not to defend the trophy. The second in the race was also a representative of France, viz., Heath, driving a Panhard car, his time being 4h. 39m. 40s. America secured the third place, with Tracy, on the Locomobile petrol racer, in 4h. 58m. 26s., and Lancia, driving a Fiat car, owing to one of the American cars colliding with him, had to be content with fourth place in the time of 5h. 0m. 31s. These are the bare results of this struggle.

For days prior to the actual race, competitors practically monopolised the Long Island roads, creating thereby considerable ill-feeling amongst certain sections of the resident population, who retaliated by placing obstructions, in some cases of a serious nature, on the highway. Fortunately no accidents occurred in consequence of these ill-advised attempts to remonstrate with the racing men, who, after all, were only doing what appears to have been permitted by the authorities.

The race itself was successfully carried through without any serious mishap or loss of human life, although accidents to cars and competitors were very plentiful. Several of the European drivers during the preliminary trial runs over the course made some emphatic complaints, in one instance almost amounting to a stand-up fight, in regard to alleged "nursing" by some of the American competitors. Both before the race and during the race the dangerous corner at Albertson was respon-

sible for several severe accidents and many more hair-breadth escapes. The course was the same as for the American Eliminating Trials on Long Island, starting from New Hyde Park, the distance being 28½ miles per circuit. This was covered ten times, making a total of 283 miles. Jenatzy on R. Graves' Mercedes secured No. 1 position in the ballot, and was therefore the first to be sent off, punctually at six o'clock. At one minute intervals the rest of the nineteen starters were dispatched. With the exception of Christie all made good starts, some exceptionally good. Lancia on the Fiat made by far the best however, getting away with a splendid run. Christie was stuck at the starting point for over half an hour, and although at times during the race his car showed signs of running well, it was of such an intermittent character that he was hopelessly out of any chance from the very first, his total elimination being when he ran into Lancia's Fiat car in the 8th round, thereby taking what was practically a certain victory from Italy and giving it to France.

At the middle of the race (at the finish of the fifth circuit) the position and full times of the competitors for the 141½ miles were as follows:—

	H.	M.	S.			H.	M.	S.
1. Lancia	...	2	2	5	7. Warden	...	2	23 46
2. Heath	...	2	15	11	8. Tracy	...	2	25 18
3. Keene	...	2	20	33	9. Chevrolet	...	2	28 41
4. Sartori	...	2	21	6	10. Nazzaro	...	2	37 56
5. Sisiz	...	2	21	45	11. Lytle	...	3	43 53
6. Hemery	...	2	22	33				

Of the nineteen starters only four were officially timed for the full course, viz., Hemery, and the others whose times we have already given. The only other three that still remained in action after Lancia retired were Nazzaro, Sisiz, and Duray, they coming

							m. s.	m. s.	m. s.	m. s.	m. s.	m. s.	m. s.	m. s.	m. s.	m. s.	m. s.	h. m. s.	m.p.h.																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																					

up to the finishing point in the order named subsequent to Lancia being timed, after which, the race was officially declared over, the public having already for some time "broken cover" throughout the course.

Hemery, the winner, made a poor run on the first round, being only thirteenth in respect to the best time, with 28m. 23s. Subsequently, however, he pulled up, making the fifth best time for the second and third rounds, dropping back, however, to ninth best in the fourth, but leading with 24m. 49s. in the fifth, from thence onward keeping steadily up towards the top, although in no individual circuit, except the fifth, did he make the best time.

Lancia, on the other hand, repeated the grand running on the Fiat which he made on the Auvergne Circuit. Had it not been for the collision, after the seventh round, due to Christie, there is little doubt that he would have simply "walked away" with the race. Commencing with a brilliant start, his times each circuit were never equalled, and moreover, not even approached. He led on the first round by over a minute, the second by nearly two minutes, and the third by three minutes, and at the end of the fourth had increased his advantage over all competitors to no less than 13m. 42s. At his fifth circuit he was 13m. 6s. ahead, on his sixth, 15m. 41s., and on his seventh, after which came his mishap, when restarting after setting right a tyre, he had no less than 20m. 57s. in hand in advance of the whole field. There can be hardly any question, therefore, that Christie's running into him from behind at the moment of his re-starting, cost him the race. Lancia's fastest circuit, and the fastest of the day, was the fourth, which he covered in 23m. 18s., the nearest approach of any other competitor to this time on any circuit being Sisz on his third of 24m. 21s. With the elimination of Lancia, Heath was left in the premier position, for the eighth circuit, but this he failed to maintain, Hemery running him very hard, and passing him in the next round, the latter ultimately winning, on his Darracq car, shod with Dunlop tyres, in the time already recorded, leaving Heath to take second place in the final. Tracy, the next in on the Locomobile petrol car, was the only American to finish, and Lancia, in spite of his accident, and the time necessarily wasted in putting his car right, still managed to get into fourth place within 24 minutes of the winner.

Some narrow escapes were reported, Foxhall Keene coming to grief at the S turn near Buli's Head by skidding on to the telegraph poles and smashing his wheel. In Christie's accident, both he and his mechanic were thrown out, sustaining fractures. Lytle, on the Pope-Toledo, also was the victim of a collision, his mechanic being ejected on to the road, and was unable to rejoin Lytle, who proceeded alone until he was able to secure another mechanic. Cedreno was another victim of skidding against a telegraph pole, Jenatzy smashed a wheel, Dingley suffered from cracked cylinder, Campbell broke his differential, Lytle ultimately was eliminated by a cracked cylinder, Duray being the one destined to find the usual dog on the course—in this case an animal considerably above the average size—with a resulting damage to his wheel.

The powerful and fast "White" racer altogether disappointed its supporters by never unfortunately getting into its paces, and finally retiring after the fourth round, the best time for a circuit being 42m. 31s. This racer sadly missed its "magician," Webb Jay, who knew so

intimately all its little points and foibles, and would undoubtedly have made it a serious element to reckon with for the rest of the competitors but for his unfortunate accident which recently placed him *hors de combat*. No doubt Walter White did his best to put her along, but perhaps under the circumstances it would have been the wisest course to have accepted the inevitable and to have stood aside from the race. In one or two quarters words of thankfulness were uttered that the master hand of Webb Jay was not at the wheel to guide the White car's destiny.

The organisation of the race was good, telephone communication being installed at distances of five miles, whilst a special "orator" was appointed to acquaint those at the Grand Stand with the progress of the race.

It is noteworthy that Hemery's car was the lightest vehicle in the race, viz., 859 kilogs., with the exception of the sister 80-h.p. Darracq driven by Wagner, which scaled 852 kilogs.

Misfortune, subsequently, on the Sunday, overtook Hemery's 80-h.p. Darracq car with which he won the race. When the vehicle was being prepared for shipment to France, a fire broke out and partly destroyed the car.

The case of disqualifying Hemery by the Italian A.C. in connection with the Florio Cup Race, was, when the Vanderbilt Race was run, still to come before the A.C. de France, who have since also disqualified Hemery from driving in France as long as the Italian penalty remains in force.

Although only one American car succeeded in getting through, W. K. Vanderbilt, jun., was so well pleased with the result of the race, as demonstrating the progress made by the American industry, that he announced his intention of creating for October next year, a new big International event, to be run in America.

Brighton to Edinburgh.—Mr. Cecil Edge last week successfully accomplished his task of driving a 6-cylinder Napier from Brighton to Edinburgh entirely on the top gear, and the time-table which we published in our last issue was adhered to throughout. Leaving Brighton at 6 a.m. Wednesday morning, Edinburgh was reached about half-past seven on Thursday evening, and during the whole of that run, which includes—as those who are familiar with the Great North Road well know—some very stiff hills, no other speed but the "top" was used, even for starting. Neither the machinery nor the Dunlop tyres were any the worse for this severe method of driving.

The car, with its passengers and luggage, weighed within a hundred-weight or so of two tons, and it was geared to 38.4 m.p.h. at the engine speed of 1,760 r.p.m. In these days of "Records" and Trials, it is difficult to devise a new test of any merit, especially for cars like the 6-cylinder Napier. Mr. Edge, how-

ever, in instituting this run—which was carried out under the observation of Mr. Straight, acting officially for the A.C.G.B.I.—happily hit upon a simple and effective scheme which should appeal to all motorists, especially those who are drivers of cars.

Impromptu Hill-Climb.—The Sheffield A.C. Handicap Hill-Climb for cars which took place on September 16th, has resulted as follows:—

		m.	s.
C. D. Leng	... 16-20-h.p. Fiat	7	4
J. H. Hall	... 12-h.p. Gladiator	8	29
J. T. Fryer	... 10-h.p. Hallamshire	8	50
Dr. H. Fletcher	... 6-h.p. Wolseley	11	25

Coupe de Compiègne.—The two days' tourist car trial recently held by the A.C. de l'Oise over a distance of 515 kiloms., starting from Compiègne, resulted in a win of the Cup by Baron Petiet, with a 30-h.p. Aries car. In Category 1, for cars under 2½ litre cylinder capacity, a 12-h.p. Gladiator obtained first prize, and was the only car classed. The weather was very bad, the roads worse, and the route selected was a severe one. A number of the competitors were disqualified, they having departed, by error, from the prescribed course. The majority of the rest were also not qualified for classification, as they did not maintain an average speed over the various sections of flat and uphill roads, as provided for by the rules, leaving only five cars and one motor bicycle in for classing. These were:—

CAT. 1 (under 2½ litres).—12-h.p. Gladiator, 1,108 points.

CAT. 2 (2½ to 3½ litres).—(1) 18-h.p. Herald, 836 points; (2) 12-h.p. Gladiator, 912 points; (3) 12-h.p. Bayard-Clement, 1,958 points.

CAT. 3 (3½ to 7½ litres).—30-h.p. Aries, 588 points (Coupe de Compiègne).

MOTOR BICYCLES.—Alcyon, ½-litre,

Gaillon Hill Climb.—For the seventh year in succession the contest on this hill, organised by *L'Auto*, was carried through on Sunday last. The distance of the test was over a flying kilometre, and 76 entries were received for this year's fixture—these including six

The six-cylinder Napier ready last week at the Automobile Club for its "top-speed" journey to Edinburgh, with Mr. Cecil Edge, who drove it, at the wheel, and Mr. Straight, the official observer on behalf of the Automobile Club, at his side.

tricar and seven heavy vehicles, both these being new classes created this year. No records were broken, the fastest time of the day being 31 seconds, made by Baron de Caters on a 120-h.p. Mercedes, and Cissac, on a Peugeot bicycle, weighing under 50 kilogs., a remarkable "dead-heat" between such a pigmy and such a giant. The unlowered record stands at 29 seconds. The best combined time, however, of 1m. 11secs. for the two hill climbs of Chateau Thierry and Gaillon, which *L'Auto* bracket together as allied events, still remains with Clifford Earp and the 6-cylinder Napier. Unfortunately Earp's car was not in its best stride on Sunday, and was 1½secs. behind De Caters' winning machine. Bablot, on his Berliet car, was at the head of the Tourists with 44½secs., and Rivierre, driving a Contal-tri, secured first place in his class with 1m. 22½secs. In the Heavy Vehicle Class, the "Automoto" light wagon proved the fleetest in 4m. 42½s.

The chief times were:—

Racers.

Heavy Cars (650 to 1,000 kilogs.).

1. De Caters (120-h.p. Mercedes), 31 secs.; 2. Villemain (120-h.p. Bayard-Clement), 32 secs.; 3. C. Earp (6-cyl. Napier), 32½s.; 4. Teste (120-h.p. Mercedes), 33½s.; 5. Stead (120-h.p. Mercedes), 38½s.; 6. Faure (60-h.p. Mercedes), 43½s.

Light Cars (400 to 650 kilogs.).

1. A. Clement (Bayard-Clement) and Hanriot (Darracq) dead heat, 32½s.

Voiturettes (under 400 kilogs.).

1. Barriaux (Vulpes), 45s.; 2. Touloubre (Darracq), 47½s.

Motor Bicycles (under 50 kilogs.).

1. Cissac (Peugeot), 31s.; 2. Guippone (Peugeot), 40½s.; 3. Anzani (Buehet), 50½s.

Tourist Cars.

- CAT. F.—18,001 to 25,000 francs.—1. Bablot (Berliet), 44½s. 2. Gaste (Radia), 1m. 7½s.

- CAT. E.—15,001 to 18,000 francs.—1. Langruber (Fiat), 1m. 9½s. 2. Marnier (Radia), 1m. 20½s.

- CAT. D.—12,001 to 15,000 francs.—1. Baras (—), 1m. 30s. 2. Aublanc (Darracq), 1m. 33½s.

- CAT. C.—8,001 to 12,000 francs.—1. Chanliaud (Gardner-Serpollet), 1m. 9½s. 2. Deguingand (Vinot), 1m. 12½s.

- CAT. B.—4,001 to 8,000 francs.—1. Thorel (Gardner-Serpollet), 1m. 15s. 2. Miormet (Gardner-Serpollet), 2m. 12½s. 3. Delaunay (Boyer), 2m. 17½s.

- CAT. A.—Under 4,000 francs.—1. Bailleau (Bailleau), 3m. 10½s. 2. Jousse (Fouillaron), 3m. 15s. 3. Folberth (Oldsmobile), 3m. 15½s.

*Motor Bicycles (½ litre).—*1. Anzani (Alcyon), 53½s. 2. Quentin (Contant), 59½s. 3. Guippone (Peugeot), 1m. 0½s.

*Tri-cars.—*1. Rivierre (Contal), 1m. 22½s. 2. Penel (Stimula), 1m. 41s.

*Heavy Vehicles.—*Automoto (light wagon), 4m. 42½s; Serpollet (30-seated omnibus), 6m. 4½s.; Brillie II. (5-ton wagon), 8m. 38½s.; Aries (3-ton wagon), 10m. 48½s.; Brillie I. (30-seated omnibus), 11m. 11½s.; Dufoure (5-ton wagon), 12m. 54½s.

Coming Events.—The Competitions Committee of the A.C. de France have decided that for 1906 the club will organise, under the title of "Circuit Européen," the already much-discussed extended tourist car trial, which will embrace Paris, Central France, Northern Italy, Lower Austria, Vienna, Prague, Berlin, Cologne, Brussels, and back to Paris. For the purpose of drawing up regulations, four sub-committees have been appointed to deal respectively with (1) classification, which will be based mainly on horse-power in relation to weight; (2) the route; (3) the fêtes and exhibitions *en route*, at the chief towns visited during each stage; (4) carriage body. In this it is suggested that a uniform type of body, varying only so far as weight is concerned, should

be made compulsory. The entire event may cover 25 days, and June or July will be the probable months selected.

UNDER the title of the "Targa Florio," a new trophy is to be offered by M. Vincenzo Florio for competition in Sicily next year. Entry is to be confined to tourist cars, of which the chassis cost is less than 20,000 francs. In the case of vehicles valued at less than 15,000 francs, the weight in complete running order must not be less than 1,000 kilogs. For cars costing 15,000 to 20,000 francs, the weight must be at least 1,300 kilogs. The route which will be selected will, it is stated, be very severe in character, and over which nothing but vehicles built in the very strongest manner could possibly hope to succeed. In order to ensure a good entry list, M. Florio announces that special arrangements will be made for conveying entered cars from France by boat at an inclusive charge of 25 per cent. of the usual freightage to Sicily.

A SIX-DAY economy test for automobiles is taking place in New York under the auspices of the New York Motor Club from October 23rd to 28th. The object is to demonstrate how economically persons may be transported between given points in motor vehicles. There are five classes, according to the selling prices of the contesting machines, ranging from cars costing 750 dollars to above 3,500 dollars. The daily runs will be from New York to Philadelphia (90 miles), back again (90 miles), to Albany (150 miles), back again (150 miles), to Southampton, L.I. (101 miles), back again (101 miles). Total distance, 682 miles. The charges to be made per person are based on the railroad fares. All fuel and lubricants are to be charged up at current rates, and repairs are to be allowed for at a specified rate per hour.

MOTOR CYCLING.

Quarterly Motor Cycle Trials.—Suggestions have been made to the Auto Cycle Club that they should hold 100 Miles Quarterly Trials for motor cycles, in similar manner to the A.C.G.B.I., for cars over the road from London to Oxford and back, taking Dashwood Hill and Aston Hill *en route*. It remains for those interested in the pastime to encourage the club to proceed further with this matter.

Sheffield A.C. Hill Climb.—The results under the Auto Cycle Club formula of the handicap hill climb for motor cycles, arranged by this club on Sept. 16th, is as follows:—

		Time.			
		m.	s.	marks.	
1.	G. D. Flather, 3½-h.p. White and Poppe ...	4	42	27	
2.	W. L. Gilder, 2½-h.p. De Dion Tricycle ...	8	27	30	
3.	F. Donovan, 3½-h.p. De Dion ...	7	11	35	
4.	J. Walker, 5-h.p. De Dion ...	4	36	47	

International Cup.—In regard to proposals of the Austrian Motor Cyclists Union for altering the regulations governing this Cup, for future years, so that the weight limit may be placed on the machine only, without tyres, or on the motor by itself, after full consideration, the Moto Cycle Club of France have come to the determination that they are not able to accept the modifications in view of the regulations as they stand in regard to the Cup. The British Auto Cycle Club, who have already submitted proposals to limit the race to makers of standard pattern machines, are willing to support the Austrian Club proposals or any others likely to eliminate the "freak" racing motor bicycle and improve the standard touring machine. It is to be hoped, therefore, that the French Moto Cycle Club will see their way to fall in with the very reasonable and, moreover, essentially sensible suggestions of the Austrian body.

THE TOURIST TROPHY RACE QUESTION.

(Concluded from page 1270.)

TABLE IV.—Relationship of Windage to Power, Speed, Road-Resistance, Gradient, and Fuel Consumption.—(Copyright.)

Gradient.	Tractive Pull Required to overcome:			The effect of "Windage."				Data, obtainable in practice with 12-b.h.p. available on the Road Wheels.							Equivalent data with 15-b.h.p. on Road Wheels.		Equivalent data with 9-b.h.p. on Road Wheels.		Gradient.
	Road-Resistance.	Gradient (i.e. gravity).	Road - Resistance plus Gradient.	Possible speed with 12-h.p. if no "Windage."	Actual Pull imposed by "Windage" at such speed.	Relative magnitude of such "Windage" to Road-Resistance plus gradient.	Power actually required to attain such "theoretical" speed.	Speed of Car.	Tractive Pull induced by "Windage" only.	Road-Resistance.	Gradient (gravity).	"Windage."	Relative Fuel Consumption (distance per unit quantity).	Speed of Car.	Relative Fuel Consumption (distance per unit quantity).	Speed of Car.	Relative Fuel Consumption (distance per unit quantity).

Tourist Trophy Car Data, assumed in Table IV.

Weight.—Chassis = 1,450 lbs, body and load = 950 lbs.
Total = 2,400 lbs.

Power. B.H.P. of engine = 18; transmission loss = 33½ per cent. B.H.P. on road-wheels = 12-h.p.

Gear.—Gradually variable change-speed mechanism, having full range.

Windage = .005V² (V = speed in m.p.h.) lbs. per sq. foot.
Cross-section of car = 12 sq. ft. ∴ Actual windage = .06V².

Road-resistance.—Draw-bar pull of 56 lbs. per ton = $\frac{1}{40} \times 2400$ lbs. = 60 lbs.

Engine-speed, Power, and Consumption.—25 per cent. more or less speed (above or below "normal") = 25 per cent. more or less b.h.p. (15-h.p. or 9-h.p. on road-wheels), and 25 per cent. more or less fuel per hour.

The above table will be found extremely valuable from three distinct points of view—all of which have an important bearing on the Tourist Trophy Race question. It not only shows (1) the speeds that a car weighing 2,400 lbs. can attain on roads having various gradients, when 12-b.h.p. is available on the road-wheels, but it also brings forward (2) the prominent part which "windage" plays in the absorption of power, and (3) the great effect which higher speeds have in increasing the fuel consumption *per mile*. The assumed data set out above—which has formed the basis of our calculations—renders our figures applicable as far as possible to the type of car for which the present Tourist Trophy rules are intended. It should be pointed out, however, that it has been necessary to work on the assumption that the change-speed-gear on the car is capable of giving *any* desired ratio in order to maintain a constant engine-speed at any car-speed, and that no allowance has been made, in the figures showing relative fuel consumption, for the reduced efficiency and for the lower proportionate h.p. which result in practice from running an engine above its normal speed—facts which were very forcibly demonstrated in connection with our recent experiments on this subject. Both these considerations tend to make our figures minimise the actual fuel-

consumption differences that there would be in practice, and the former renders those referring to speeds (in miles per hour) much more regular than they would be with existing vehicles.

In column 1, the various gradients are arranged in order of steepness, from a descent of 1 in 3 to an ascent of 1 in 3, and these are, for convenience of reference, repeated again in the last column.

In columns 2 and 3, the draw-bar pull resulting from road-resistance and from gravity (gradient), respectively, are set out in lbs., while in column 4, the combined effect of the two is given.

The 5th column indicates the speed which the car could attain, with 12-b.h.p. available on the road-wheels, if there were no such thing as "windage"—i.e., if the car were travelling in a vacuum. It will there be noticed that on a down grade of 1 in 40, the power required to overcome the road-resistance is balanced by the power derived from gravity, and that therefore the speed becomes infinite. In the next column (6), is given the actual resistance of the air, on a still day, (windage) at such "imaginary" speeds, these figures, therefore, representing the pull in lbs. that had been neglected in column 5. Its relationship to the pull required for overcoming road-resistance as well as gravity is given separately in the succeeding column (7). Finally, in this portion of the table, column 8 shows the b.h.p. that would have to be available on the road-wheels for the car to attain the speed given in column 5.

In column 9, the real speed that can be attained in practice is indicated, "windage" having been taken into account in these calculations and its value in lbs. set out separately in the following column (10). The enormous effect of the air, when travelling fast, is seen to be remarkable, for whereas in column 5 we find 224 m.p.h. for a down grade of 1 in 60, yet in column 9 the possible speed is only 113.8 m.p.h. down a hill of 1 in 3.

The next three columns (11, 12, and 13) are particularly interesting—corresponding as they do with columns 2, 3, and 10—for they show the manner in which the original 12-h.p. on the road-wheels is expended, and indicate precisely how much power is absorbed by road-resistance alone, by gradient alone, and by windage alone; the sum of the three figures in these three columns is, of course, invariably 12. On a down grade of 1 in 40, for instance—when (as already pointed out) the road-resistance is exactly counterbalanced by gravity—the whole of the 12-h.p. goes to overcome the windage, which (at 42.2 m.p.h.) requires a draw-bar-pull of 107 lbs. Then comes a column (14) in which the corresponding fuel-consumption is expressed in miles per unit of quantity, these figures being based on the assumption that the car can run one mile on one unit of fuel when it is travelling at 34.5 miles per hour and when the engine is developing 12-b.h.p. on the road-wheels—i.e., when the car is running at normal speed on the level and the engine is fully loaded (18-b.h.p.) at its normal speed. The figures are, of course, proportionate to the rate of travel, since the fuel consumption per hour would remain constant, and they simply show the effect of gradient (and windage) on the consumption per mile.

Columns 15 and 16 correspond with columns 9 and 14, except that they are based on an assumed power of 15-b.h.p. (instead of 12-b.h.p.) on the road-wheels. They not only show that a 25 per cent. increase of power makes very little difference in the speed attainable by the car when that speed is already high, but they also emphasise the fact that, such as it is, it is accompanied by a material increase of fuel-consumption per mile, excepting when the car is travelling quite slowly. In practice, if the engine were accelerated to 25 per cent. above its normal speed, the b.h.p. would not on most cars be increased by as much as 25 per cent. (18-h.p. to 22½-h.p.), and the fuel consumption per hour would undoubtedly be increased by more than 25 per cent., but we have assumed that both these performances are achieved, and, therefore, a comparison of column 16 with column 14 only shows the extent to which the mileage per unit of fuel is decreased by windage alone; the difference would, therefore, be very much greater in reality.

The converse case is dealt with by columns 17 and 18, column 17 corresponding with columns 9 and 15, and column 18 corresponding with columns 14 and 16. Here, the basis of power is taken as being 9-b.h.p. on the road-wheels—a decrease of 25 per cent. Again, it has been assumed that the fuel consumption per h.p. per hour is the same as before, and, in order to make the figures applicable to a car in which the engine speed has been reduced to 25 per cent. below the "normal," it must be further assumed that the b.h.p. is exactly proportionate to the speed, i.e., 13½-h.p. The gain shown in mileage per unit of fuel is therefore only that which results from "windage." The difference, however, is very marked, for whereas our unit of fuel is seen to take us a mile on the level at normal engine speed, it only takes us that distance on a down grade of 1 in 60 when the engine is accelerated, but, on the other hand, takes us the same distance on an up grade of about 1 in 100 if the engine speed is reduced by 25 per cent. For the extreme case of descending a hill of 1 in 3 the mileage figures are 3.3, 2.66, and 4.38 per unit of fuel respectively, for normal speed, for accelerated speed, and for reduced speed of engine.

The Application of Table IV. to the 1905 Tourist Trophy Race.

On the basis of Table IV., by applying it to the Tourist Trophy course in the Isle of Man, and taking the gradients as being those approximated in our Table III. (p. 1117, September 9th), we find that if our assumed car were to have 12-b.h.p. available on the road-wheels, then it could complete the whole course (208.5 miles) in 6h. 35m. 52s.—or 1h. 38m. 58s. per circuit—this representing an average speed of 31.7 miles per hour. If, however, the engine were accelerated by 25 per cent., and gave 15-b.h.p. on the road-wheels, the whole course would be covered in 5h. 52m. 48s. (a gain of 43 mins.) which is equal to 1h. 28m. 12s. per circuit—or a mean speed of 35.55 miles per hour. On the other hand, if the engine speed were reduced by 25 per cent., and gave 9-b.h.p. on the road-wheels, the car would take 7h. 39m. 48s. for the entire course (a loss of 1h. 14m.), which represents 1h. 57m. 27s. per circuit, or an average speed of 26.7 miles per hour. The further useful data, derivable in the same manner, is that if the fuel-consumption per hour were proportionate to the b.h.p. developed by the engine, the car would consume almost exactly one gallon more (10½ gals.) for the whole race under the accelerated conditions, and almost exactly one gallon less (8½ gals.) than normal if it ran with the engine speed reduced; these figures are founded on the supposition that the fuel-consumption would be 9½ gallons for the race if the engine ran at normal speed, i.e., giving 12-b.h.p. on the road-wheels all the time. A comparison of these theoretical results with the actual performances of the cars which took part in this year's race is very instructive, for they approximate very closely to one another.

OUR CORRESPONDENTS' LETTERS.

There is yet one matter, in connection with this important question of the Tourist Trophy type of contest, that should be dealt with before concluding the present series of articles, the appearance of which has been delayed somewhat owing to recent pressure upon our columns. We feel that some further remarks and explanations are required upon one or two of the points raised by our correspondents in their published letters, and that it would be useful, in view of future rules and regulations, to refer to a few of the considerations involved. It is unnecessary to give anything like a full summary of the various opinions expressed in those letters, because nothing could serve their purpose better than the letters themselves. It would indeed be almost impossible to do so, since our various correspondents fortunately looked at the question

from such very diverse points of view. But we would draw attention to the fact that on several of the points at issue, opinions differed enormously, and that evidently a considerable number of practical data was then needed before anything like unanimous accord could have been expected. Even now that the first Tourist Trophy Race has been run, and that its many lessons are therefore available, we think the following references to our original article, and to our correspondents' letters, will serve a useful purpose—even if that purpose should chiefly be a clearing of the ground in readiness for fresh considerations.

"Durability."

Referring to one of those matters on which it is evident, from the "views and opinions of our readers," that our original article was not sufficiently lucid, it should be pointed out that the "durability"

of a car is to a certain extent tested in the contest, even though the race extends over such a short period. In an ordinary race, the loss of power brought about by such additional friction as might lead to undue wear and tear of the mechanism would not necessarily have any serious effect on the result, since the speed capabilities of the car might well be maintained, in spite of it, by increasing the power of the engine. Such compensation would, however, increase the fuel consumption; therefore any such loss of power would, in the Tourist Trophy race, constitute a direct handicap.

"Consumption" or Cylinder Dimensions.

Another point upon which special emphasis may not be out of place concerns the relative merits of taking "fuel consumption," or "cylinder dimensions" as the basis for limiting the power of the engines. Quite subsidiary drawbacks to the latter method are those of having to check the maker's figures, and the premium that might be put on high-speed engines (*per se*), but the really serious objections, in our opinion, are that a direct incentive is given to the construction of uncommercial engines, and also that there would be a great inducement for the driver to make a practice of "racing" his engine as much as possible. It would, for instance, be quite possible to fit an auxiliary pump-mechanism to the engine for forcing larger charges into the cylinders. Even if such an obvious "freak" device were barred by the rules, it might still be found advantageous to employ an abnormally high compression, and merely prevent it from occasioning pre-ignition by skilful manipulation of the engine—by always keeping it at a high speed during the race.

Divided Bodies.

Concerning one of the suggestions made by us for modifying the rules in future years, the sole reason for proposing that the body should—for the purpose of the race *only*—be divided into four separate parts, was that it would prevent any evasion of the rules relating to the respective weights of the chassis and of the body. In the majority of cars now used, the body does not materially stiffen the frame, and consequently it might be well to prevent it from being made to do so on a "freak" car. It is quite conceivable that a strong metal body, securely fixed at numerous points to an otherwise flimsy chassis, might enable the car to withstand the strains imposed upon it during the race, but that with an ordinary body it would stand no chance of holding up in a severe trial of any kind. It might, moreover, be held that the short duration of the race renders it desirable that the ordeal should be made as searching as possible, and that, therefore, the removal of whatever stiffening an average body may afford, is desirable in the interests of competitors and public alike. It is not, however, a matter of much importance, and would cease to have any at all if the "maximum" weight limit of the chassis were to be abolished.

Gradually-Variable Gears.

The proposal to arbitrarily restrict the number of "speeds" has not only brought up the question of gradually-variable change speed

mechanisms, but is in itself one which demands the most careful consideration. Gradually-variable gearing being practically non-existent at the moment—at any rate, from a commercial standpoint—need not, we think, be taken into account in next year's rules too seriously. Apparently there is no reason why such mechanisms should be in any way excluded, but it will be quite time enough to frame any special rules that may be needed for them when they do arrive upon the scene and demand attention. Such "gears" are obviously highly desirable if they can be rendered thoroughly successful, and it is only right that their makers should benefit in the Tourist Trophy—as they unquestionably might do.

Gear-Box Restrictions.

What is of vastly more importance just now, however, is as to how many "speeds" should be allowed in the ordinary type of gear-box, and another burning question affects the relative ratios of the different "speeds." It is a well-known fact, which is amply borne out by our recent tests, that every additional intermediate "speed" in the gear-box would be equivalent to an additional allowance of petrol in the fuel-tank, on such a course as that selected for the Tourist Trophy Race in the Isle of Man. It would, in fact, enable the engine to be run for longer periods at the most efficient speed and load; and would, therefore, materially assist the competing car fitted with it. In view of the fact that no particular ingenuity or invention is required for increasing the number of "speeds" in the ordinary type of gear-box, and since four speeds are at present found to be sufficient in practice, it would certainly seem but fair that the number of "speeds" on all Tourist Trophy cars should be limited. Practically any of the cars entered could have been provided with five or six "speeds" if the practice had been deemed advantageous to the buying public, but unless they were all so fitted, they would be competing on anything but equal terms.

The other "gear-box" question arises because there is a distinct advantage to be gained in the way of fuel consumption by making the top "speed" so enormously high that the speed of the engine can be kept quite low when the car is running down hill, and that dangerous racing can then be indulged in. In ordinary touring practice, such a provision has no material merits, since *cost* of fuel is far from being a serious consideration, and, therefore, it would seem advisable that some rule should be introduced in future to restrict the relative ratios of the "speeds" on all competing vehicles.

Another possible difficulty that may have to be dealt with, if the Isle of Man course is always used for the event each year, is that certain (otherwise unusual) gear ratios may be found specially suitable for that particular route. As has been shown already, the contour of the road is such that this would not hold good, to anything like the same extent, if the cars had to travel over it in the opposite direction as well, and the idea, therefore, suggests itself that the direction might be left undecided until the actual start is made, or that if the race were to extend over more than one day, the direction might be reversed on the second day.

TOURIST TROPHY RACE.—A pleasant impression. General view of Douglas from the sea, showing Snaefell over which the Tourist Trophy cars had to climb four times. In the distance, just over the mast of the boat in the centre of the picture, Snaefell can be identified.

Noisiness.

Difficult as it undoubtedly is to find a satisfactory method for preventing any unduly noisy cars from taking part, it is yet very generally agreed—as shown by the numerous letters from correspondents—that such a step is advisable. It may, indeed, be almost regarded as a necessity for ensuring the complete success of a touring-car contest, since, unfortunately, effective exhaust-boxes usually tend to reduce the power and efficiency of petrol engines, and there is therefore a direct incentive to one class of noisiness. It is a matter that will need attention when the time comes for a revision of the present rules; they are now defective, at any rate, in that they do not preclude the use of relief-valves in the exhaust-pipes, for allowing the back pressure to be removed at the will of the driver.

Controls.

Although the establishment of "controls," in the ordinary sense of the word, is doubtless unnecessary, as well as being open to the objection that calculations are involved in determining the true position of each car in the race, yet there are reasons why it might be wise to stop each car momentarily at certain points on the route. Dangerous spots would preferably be selected, thus reducing the risks of accident happening, and another advantage would be that the stopping and restarting powers of the cars would be well tested. Incidentally, moreover, it would assist in that timing of the cars at fairly frequent intervals which is so desirable, and it would enable the officials to affix "lap-indicating" labels in accordance with Mr. Johnson's excellent amplification of the system proposed in our previous article.

Change of Drivers.

Generally speaking, there is apparently a very strong feeling against the suggestion that different drivers should be entrusted with each car on different days—assuming that the race *could* be extended over one day. The point at issue really resolves itself into the question as to whether the main objects of the event are to demonstrate the relative merits of each car, and are to introduce a sporting rivalry between the drivers, or as to whether it is the combined and inseparable merits of car *plus* driver that are to be put on trial. From the purchaser's point of view, it is the car only that interests him, since he requires a good car for his own use only, and from the driver's point of view, anything that will enable him to demonstrate his own superior skill would doubtless be welcomed by him. To them, therefore, our suggestion would doubtless be very acceptable. From the manufacturer's point of view, however, the case is rather different, for it is but natural that those commanding the services of a specially good driver should prefer to benefit by his services to the full. We might point out that it would not be necessary for a firm entering more than one car to provide more than three drivers in all, because three drivers could even be employed on three cars on three separate days without allowing any car to be driven by the same man twice. The point only arises, however, in the event of the race being extended over more than one day in future years, but we are extremely glad to see that the consensus of opinion expressed by our readers in their letters is strongly in favour of that course being adopted, if it is possible to arrange it.

Other Classes of Vehicle.

As can be seen from the details which we have given of the competing vehicles taking part in this year's race, the type

now specified by the Tourist Trophy rules may practically be said to be one having an engine of about 18-h.p., taking a fairly light touring body, and capable of maintaining an average speed well above the present legal limit. It is, in fact, a class of vehicle that is much in demand, and that can be sold at a moderate figure. Obviously, however, it is only one class amongst several, and is therefore one which some of the best known manufacturers do not build. Apparently, therefore, the same reasons that have led to the organisation of this race for "25 mile per gallon" vehicles would warrant similar events being held for other types of vehicle, and we might therefore expect as much success to attend the institution of races for, say, "15-milers" and for "35-milers." The former, with suitable weight-limits for body, load, and chassis, would include those luxurious touring vehicles which are so justly popular with the wealthy, and the "35-milers" would include two-seaters and the "poor man's" light car. The races for each class would naturally be held on quite different days from one another, and the number of "classes" would depend, from time to time, upon what was found advisable.

Whether there were only three or even more "classes," the tendency towards standardisation of types would be welcomed by all those interested in the automobile movement. Motorists would have every chance of holding their own local sporting contests on well understood and sensible lines, whenever they wished to do so. The manufacturer would no longer be called upon to go to the expense and trouble of taking part in all and sundry events, in each and every part of the country. And—not by any means of least importance—the amateur driver would learn more about the proper way to drive his car than he would do in years as at present.

Specified Weights and Dimensions.

Although it is early yet to come to any definite conclusion concerning what the weight limits should be for a "25-mile per gallon" standard vehicle, particularly as opinions differ on the subject so widely, yet it should, we think, be borne in mind that one of the few reasons for specifying a maximum weight for the chassis at all is to prevent a certain kind of "freak" car from being entered. The risk, which is extremely remote, is that some complicated auxiliary machinery—such as a compressed air plant with pumps and a pneumatic engine—might more than compensate, from a race-winning point of view, for the additional weight carried, and thus be fitted to a car for the sole purpose of securing the Trophy. Otherwise it would not really matter if one chassis were somewhat heavier than another, especially as it would automatically suffer from the direct handicap resulting from its additional weight. It would, therefore, seem as though the chassis weight might well be altered to admit those of from 1,300 lbs. (as now) to at least 2,000 lbs. (instead of 1,600 lbs.)

It is hardly necessary to add anything to what has already been said by us and others on the subject of the specified weight of the body and its load. Opinions differ, some thinking that 950 lbs. is too much, and others that it is too little. There is, however, Mr. Wilson's suggestion that each car should be made to carry a glass screen, so as to discourage high maximum speeds, and we think that this deserves careful attention. As he points out in his very interesting letter, the effect of "windage" increases very rapidly at higher rates of travel, and consequently a more equitable average speed would have to be maintained by all competitors.

AERONAUTICS.

ON the 12th of the month the Lebaudy airship gave a further, and in many ways the most significant demonstration it has yet provided of its magnificent capabilities. It executed a regular military reconnaissance between Toul and Nancy, returning to the starting point in 2h. 20m. With Messrs. Rey, Juchmès, Capt. Voyer, and Commandant Juillien, head of the engineering staff of Toul, the airship started on its first strictly military service at 7.30 in the morning under anything but favourable conditions, for there was a thick fog and high wind. Fortunately she had not been long in the air when the sun dissipated the mist, and enabled the engineers to demonstrate to Commandant Juillien what a thorough reconnaissance of a hostile force or hostile works of defence the airship would enable its possessors to effect. Maintaining an average elevation of about 100 metres, the Lebaudy passed over the great works and

entrenchments surrounding Toul, and beat against the north-easterly wind to Nancy, where she went about above the town saluted by the plaudits of the multitude, and started back again for Toul, accomplishing the return journey in 41 mins., as the wind then somewhat favoured her; 423 kilos. of ballast were carried, and of these only 100 were thrown out, 30 being accounted for by the process of mooring, so that, had it been necessary, it is obvious the airship might have maintained herself in the air for at least four times as long as she was actually up.

This performance, which ranks with Lebaudy's best exploits from the purely physical point of view, is epoch-making in the history of navigable ballooning, as it is the first occasion on which an airship has ever been used for a reconnaissance on strict military form, starting from a certain point, and returning to it again, in spite of adverse atmospheric conditions, and a considerable breeze.

CLUBS AND ASSOCIATIONS.

Blackheath A.C.—A pleasant termination of the club's out-of-door fixtures, which was well attended, took place last Saturday when a circular run terminated at the Bull Hotel, Chislehurst, where about fifty sat down to tea. An informal meeting was subsequently held, at which Col. H. C. L. Holden, R.A., F.R.S., took the chair, when the prizes won at the club's hill-climb at Ightham on July 8th, and at the gymkhana on September 2nd, were presented, consisting of carriage clocks, claret jugs, and other useful articles. Subsequently music and an impromptu dance brought the proceedings to a close at about 8.30 o'clock.

Ladies' A.C.—On Thursday next week, the Honourable C. S. Rolls will give an illustrated lecture before the members of the club, entitled "Historical Reminiscences and Roadside Experiences," which will be followed by biograph pictures of recent racing events. The series of technical lessons which were much appreciated last winter are to be repeated this season. The six lessons will again be given by Mr. R. Sedgwick Currie, the club engineer, and will be held respectively on November 8th, 15th, 22nd, 29th, December 6th and 13th.

Manchester A.C.—The last run of the season took place on the 7th instant to Nantwich, when, although the weather was extremely bad, over twenty cars assembled to do honour to the occasion. Nearly seventy members and their friends were present at the Brine Baths Hotel in the afternoon prior to starting on the home journey. The club's first house-dinner takes place on November 1st, and will be followed by a smoking concert. The second is down for December 4th, to be followed by a Paper by Dr. W. R. Ormandy, on "Explosion and Flame in Relation to Motor Car Engines."

North London A.C.—The club's first annual dinner will take place on November 25th, at the Midland Grand Hotel, when a special programme for the entertainment of the guests will be arranged to follow. Colonel Bowles, M.P., will occupy the chair, Mr. A. W. Gamage being in the vice-chair.

Notts A.C.—The winter season of this club was inaugurated on Friday last week by a very successful supper at the Black Boy Hotel. The meeting, which was well attended and was presided over by the President, Mr. Charles Hardy, proved of considerable interest amongst the members, it being the occasion for the distribution of the prizes awarded in the various club competitions decided during the past season. These included the Wilson Cup (which was disputed on the Clipstone track, Welbeck), the Foster Cup competition prizes, and the two Ab-Kettleby Hill-climbs

awards. A surprise was sprung upon the meeting by the presentation to Mr. S. F. Edge of a gold medal, in recognition of his sportsmanlike courtesy in sending his racing Napier car down to the Skegness Meeting. In regard to this meeting Mr. Booth Grainger, the hon. secretary, announced that, in consequence of its great success, permission had already been received from the A.C.G.B.I. to hold another meeting there next year.

Scottish A.C. (Western Section).—The annual autumn meet took place at Ayr last Saturday. There were fully fifty cars present in the enclosure at the Station Hotel, where the party took lunch. The day was cold, wet and stormy, and the turnout was consequently a large one under the circumstances. In deference to considerations of public policy, the gathering in Glasgow, and the procession through Glasgow, *en route* to Ayr, which has taken place in connection with this event for some years, "in commemoration of the passing of the Light Locomotives Act, 1896," was this year abandoned.

CORRESPONDENCE.

ENGINE BRAKING.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I am sorry that the results which I sent you in reference to the census which I had taken in regard to the best system of connecting up brakes and engine appears to have been slightly misunderstood by some of your correspondents.

They appear to think that I have only recently taken to using a car in this way myself; this, however, is a slight mistake on their part, and I am afraid that they cannot take credit to themselves for having used the principle prior to myself. My own Napier cars since 1900 have always been so used, but the alternative system is one that was provided for by the French Government, and it was necessary for a car to conform to these conditions to be officially passed as a type in France, and without such passing, it was not legal to run the car on French roads.

For the convenience, therefore, of owners of Napier cars who used them in France, we made them so that they would conform to French law, but at the same time we made an arrangement so that either brake can be disconnected from synchronising with the movements of the clutch.

Finding, however, that many people were beginning to use their cars in what I had found to be the best way, I had the census taken, which I communicated to your paper for the information of all automobilists. I had no idea of claiming priority of the idea, but cannot allow your present correspondents to think that they can claim to be first when such is not the case.

Yours truly,
S. F. EDGE.

Oct. 14.

MOTOR ROAD ROLLER IN ST. JAMES'S PARK.—The latest sphere of the petrol motor is the propulsion of road-rollers, and the first of these machines was exhibited by Messrs. Barford and Perkins at the last Park Royal Show, and is now in use in St. James's Park, which is the scene of our photographs above. The roller is water ballasted and is propelled by a single-cylinder petrol engine.

Motor omnibuses are not only increasing rapidly in London, but in country districts in all parts of Great Britain, their enormous mobility and convenience is becoming appreciated more and more daily. A service which was agitated for over a long period by the local residents has recently been inaugurated by Messrs. John I. Thornycroft and Co., Limited, between Farnham and Haslemere Stations, in connection with the London and South-Western Railway Company. We are able to reproduce this week photographs of these new public cars, one being seen in the above passing over the level crossing at Farnham.

Continental Touring by Motor 'Bus.—Perhaps the most enterprising personally conducted tour which has ever yet been arranged is being organised by the London Motor 'Bus Company, who are now booking seats for a tour through France to Monte Carlo and Mentone on one of their newest "Vanguard" 'buses, of the type which has become so popular on the route between Waterloo and Cricklewood. The whole tour will occupy thirty days, and will commence on the 18th November, the charge for the trip, which will embrace Rouen, Orleans, Montelimar, Avignon, Orange, Marseilles, Hyères, and St. Raphael, returning *via* Grenoble, Dijon, and Paris, being £52 10s., which includes not only first-class by boat across the Channel, and by rail from London for those who prefer so to travel, but also hotel accommodation, travelling tickets, meals *en route*, and the services of a competent conductor. Only sixteen passengers will be booked, so that whenever the weather is unpropitious there may be adequate room inside. With the same object in view, the personal luggage carried on the motor 'bus will be limited to about half a hundredweight per passenger, though any greater amount which the tourists desire to take will be sent for them free of charge ahead by rail to the different stopping places. The whole thing is a most original departure, and we wish every success to the enterprising undertaking of the Motor 'Bus Company. In any case, it will provide a triumphant object lesson on the reliability of the motor 'bus.

The Tramway Octopus.—What the tramway people will do if they are not stopped is pretty well demonstrated by

the sad case of the Kingston Bridge, which is one of the narrowest bridges over the River Thames. It is only 25 ft. wide altogether, and when the footways are subtracted, a carriage way of 16 ft. 9 in., just 9 inches more than the narrowest road along which motor cars are allowed to run, is left over. Across this narrow pass have been put down two lines of tram rails, so that when the trams are in possession of the bridge, it is perfectly obvious that nothing else can attempt to cross from one direction or the other, as between the outer rail on one side is a space of only 15 ins., and on the other 24 ins. It is no wonder, therefore, under the circumstances, that a petition has been presented to the Board of Trade requesting that tram cars may not be allowed to run until the bridge is widened. This is the borough, by the way, in which two separate attempts have been made to induce the Local Government Board to impose the 10-mile limit on motor cars.

A New Form of Police Trap.—A novel form of *police trap* is reported in a local paper. In this trap, as it happened,

it was the policeman who was the victim. The report is as follows:—

"A Leyton policeman came across a rambling donkey on the highway, and decided to take it into custody.

"When he got within a few yards, however, the donkey reared on its hind legs, jumped at the officer, tore his trousers and kicked out in all directions.

"At Stratford the moke's owner was fined for allowing it to stray."

1 person killed per 2,772,000 miles travelled by motor cars.

1 person injured per 125,000 miles travelled " "

The above are results obtained from data collected by the "Joint Committee," from members of the A.C.G.B.I. and Motor Union.

One of the 24-h.p. standard single-decked Thornycroft 'buses which are running in connection with the London and South-Western Railway between their Farnham and Haslemere Stations, the 'bus loading up at the Royal Deer Inn. The road over which this service runs is of a very severe nature and is traversed twice daily. Since its start early in September, the distance travelled by this omnibus is over 1,500 miles, the schedule time table being strictly adhered to throughout.

Nationalisation of Roads.—Mr. Rees Jeffreys has adopted an opportune moment for reiterating in the form of an interview his views on the road management question, which he has so ably and persistently maintained for a considerable period. The expression of Mr. Rees Jeffreys' views was evoked by the suggestion put forward by a certain Colonel Lockwood, M.P., that the roads of the country should be "pooled." Colonel Lockwood was not by this expression referring to any aqueous method of dust elimination by flooding or otherwise, but to a proposal that the maintenance of roads throughout the country should come out of one fund, to which motorists should be made to contribute handsomely. Mr. Jeffreys' view is that:—

Sooner or later the State would assume more responsibility for the upkeep of main roads. Even at present it contributed very largely to the maintenance, and it was altogether incorrect to say, as some people constantly reiterated, that the farmers were the chief contributors to their upkeep. Local taxation was regularly assisted by Treasury grants, but as these grants were not earmarked, the fact was unfortunately often lost sight of. The Roads Improvement Association had always maintained that the State should provide a definite proportion of the cost of maintaining the main trunk roads on condition that they were kept up to a certain standard of efficiency. A similar system had been found to work well in the case of the police, and there was no reason why it should not do so in regard to road administration.

In reply to a question as to whether motorists should not pay a special amount to road maintenance, it is satisfactory to find Mr. Jeffreys replying that "in his view they undoubtedly paid more than their fair share at present, as car owners really did much less to injure the high roads than other road users."

We have always supported Mr. Rees Jeffreys and his roads propaganda, but one certainly wonders at times why the French system of control and support of all the

During the tour of Their Royal Highnesses the Prince and Princess of Wales in India, provision has been made for every possible requirement. Special balloons are being sent out to enable birdseye views to be obtained of various typical cities of India, and motor cars are also to be brought largely into requisition. The above well-designed model has been dispatched to Bombay for the use of Their Royal Highnesses. The car is one of the latest Argyll models, it having been specially constructed at Glasgow, under the order of the Earl of Shaftesbury. The car is painted cream colour and upholstered in blue and has a specially-designed canopy with sun-blinds and windows. It is seated for seven.

main trunk roads of the country by the State should not be adopted in this country, or at any rate inscribed upon the banner of the Roads Improvement Association. Perhaps it is mere despair in regard to the chances of such sweeping, though necessary reform that prevents this from being done.

This view we are pleased to see is taken by Sir Charles MacLaren, M.P., who stated at a recent meeting of the last Chamber of Commerce:—

"I have long been of opinion that main roads ought to be taken up by a national authority. The subject is now becoming of pressing importance, inasmuch as motor car traffic, which monopolises so many of our main roads, and which, no doubt, renders their upkeep more expensive, is not a local traffic, but, having regard to the long distances traversed, national in character."

MR. LEVESON SCARTH, who is ever ready to wield his powerful pen on behalf of the automobile movement, has written to a recent number of the *Onlooker* a letter, from which we cull the following admirable passages:—

But take the wider point of view. Motoring is not a pastime like coaching, destined always to remain the recreation of the few. It is the greatest discovery in locomotion for the million since the advent of railways. It will, when developed (say in ten or twenty years' time) change the whole aspect of the habitable world. It is practically annihilating distance and enabling people to live where they like instead of where they must, to enjoy the country whilst they work in the towns, to range at will for forty miles round their houses—everyone can fill in the advantageous possibilities for themselves.

The "rich," who are now so hateful to writers who deplore their "brutality," are merely pioneers in this beneficial movement, unconscious perhaps of anything so lofty as a mission, but nevertheless pioneers. Their expensive experiences are teaching motor car makers, in the only really valuable school, how to remedy defects, to strengthen weak points, and finally to evolve a machine of some standard type which they can in future manufacture in considerable numbers, and, therefore, profitably and cheaply.

Many persons do not desire any such change. I condole with them on their misfortune in living a century too late for their own comfort.

Many unreasonable persons who wish for the end cavil at the means. They would gladly welcome cheap and trustworthy cars, with tyres that would never give trouble, and engines that would never break down, but they revile and fine those very persons whose money and energies are evolving for them exactly what they eventually want.

THE PRINCE AND PRINCESS OF WALES' TOUR IN INDIA.—A view from the front of the special Argyll Car shipped to Bombay for the Royal use.

The new "Arrow" line of omnibuses, which are plying between Charing Cross and Putney, are running very successfully since their inauguration, our photograph showing one of the first put on the road. These omnibuses, which are put in service by the London and District Motor 'Bus Company, Limited, have a Straker-Squire chassis, with a four-cylinder engine, the carriage portion being by Messrs. Dodson.

1906 Motor Boating.—A meeting of the joint committees of the British Motor Boat Club and Motor Yacht Club was held last week, when there were present: Lieut. H. G. Vereker, R.N., Messrs. F. C. Blake, H. T. Arnott, and R. Denys Dundas (representing the B.M.B.C.), Lieut. Mansfield Cumming, R.N., Messrs. Linton Hope, Bernard Redwood, T. Thornycroft and G. F. Sharp (representing the M.Y.C.).

Lieut. H. G. Vereker was in the chair.

It was unanimously decided that the foreign clubs should be asked to appoint a delegate to discuss next year's programme, so as to avoid clashing of dates during the forthcoming season.

It was also unanimously decided to ask the Marine Motor Association to keep a register of boats and allot a registered number to each one, charging a small fee for the same.

A GERMAN, of the euphemistic appellation Smeltz, on observing Frederick Bartley cleaning, or attempting to clean, a motor car with paraffin at the Hampstead Garage, suggested that petrol would be more effective. Smeltz thereupon syringed the car and engine with petrol and proceeded to go home, the lamps of the car being lighted at the time. He had hardly left when there was a loud report, the whole place appearing to be enveloped in flames, and Bartley rushed out with his clothing ablaze, and subsequently died from the burns. We believe that Smeltz is still at large without a keeper.

Leeds Police and Motor Cars.—A similar example of magisterial good sense

provided by the stipendiary magistrate is, before whom Mr. C. P. Wilson, secretary of the Yorkshire Automobile Club, was arraigned for causing an obstruction by leaving his motor car by leaving it standing a time variously estimated from ten to fifteen minutes, outside the Great Northern Hotel. The magistrate decided in favour of the defendant on the evidence only of the prosecution, and said that he always considered that it was not right to summon a person for an obstruction unless they had been warned or told to move on. It was then that obstruction became wilful, and he had always said that convictions should not take place if people were merely warned without being warned. There must be some evidence of actual obstruction, and there was none in this case, and he accordingly dismissed the summons.

A petrol blaze which occurred at Cornhill last Tuesday, close to the Royal Exchange, is a sad example of the evils that result from attempting to deal with a petrol fire by the ordinary methods of the fire brigade. A motor van laden with a number of petrol cans, most of which we understand were fortunately quite empty, was proceeding along Cornhill, when from some unknown cause flames burst out all over it, the petrol cans exploding one after the other, a considerable quantity of petrol flowing on to the street. The fire brigade, which was soon on the scene, played upon the conflagration with hose pipes, the result being that the escaped petrol was caused to flow on the surface of the water a considerably extended distance along the street. Ultimately sand was procured and the conflagration extinguished.

Lurries for motor ambulance work are very necessary helps to automobile repairers. Notice of a bad smash-up requiring prompt assistance, often causes considerable inconvenience by reason of the difficulty of obtaining a suitable conveyance for bringing the car into "hospital." Most of the up-to-date repair works have now acquired this very necessary piece of "furniture," and the above illustrates a Milnes-Daimler lorry which has just been adapted by Messrs. Rennie and Prosser, Limited, of Glasgow, for their motor ambulance work. It is fully equipped to undertake breakdowns on the road, and our photograph was recently secured upon the occasion of its arrival at the firm's works with a disabled car.

THE Executive Council of the Urban District Councils Associations is gathering its forces and inviting U.D.C.s to consider the evidence to be put before the Royal Commission on the Motor Car Acts.

THE New South Wales Legislative Council have passed the Government Motor Omnibus Bill through the Committee stage, during which period an amendment was carried, providing that motor omnibuses shall be subject to the ordinary traffic regulations, except with regard to licensing.

A FINE testimonial for police stop-watches was provided recently at the police court at Norton, when Mr. Herbert Pickles, of Bradford, was summoned for driving over a measured quarter of a mile at upwards of twenty-three miles an hour. Two policemen came up to give evidence, each armed with stop-watches, but as the stop-watches differed by $\frac{2}{3}$ secs. in their indications, the bench dismissed the case, preferring to rely upon the defendant's speedometer, which showed the car to have only travelled at eighteen miles per hour.

SOMEONE—presumably a humorist—suggests that a good name for the motor 'bus would be a "buzzer," on the analogy of a "whizzer," which, he says, has become the recognised name of the electric tramcar. If these names are to catch on, a Londoner's diary will make interesting reading in years to come. It will probably puzzle philologists of the future to decipher such an entry as this: "Tubed from Bank to Tottenham Court Road, 'buzzed' to Elephant, and 'whizzed' home."

COURT recognition of the motor car has developed to such a degree that, it is stated in the general Press, one of the unwritten laws of Royal entertaining is that any of his subjects whom King Edward honours with a visit are expected to have a motor car at his disposal in case of need, either for passenger or for baggage service. As a matter of fact, the King himself almost invariably takes his own car and chauffeur with him, but when Royal messengers arrive or depart it is expected that they will be accommodated with an automobile.

THE motor car horn is surely loud enough, in all conscience, for the purposes which it has to fill, and the inventor of the motor siren may certainly lay claim to belonging to that type of genius who makes a speciality of inventing things that are not merely not needed, but are positively noxious. At least this appears to be the general opinion of the inhabitants of Suresnes, just outside Paris, who are organising a crusade against the use of the siren. A siren is driven off the engine, and it emits a howl (when the engine is running fast) which can be easily heard, so the Suresnes people say, five miles off. We believe there have been some attempts to introduce this disturber of the peace into this country. Considering the amount of hostility that the automobile movement has quite unjustifiably evoked already, we trust an organised attempt will be made to put a stop to the introduction of such an wholly unnecessary innovation that can only have the effect of making every body justifiably furious with automobilists who use it.

AMONG the humorists who are making anti-automobile-mania look even more ridiculous than it otherwise would, one who has adopted the *nom de guerre* of "Pulvis" suggests that motor cars should, in future, be compelled to raise a dust in front of them instead of behind them, as, in that case, the occupants of the cars would have more consideration for the effect they produced. Doubtless they would, and if "Pulvis" can succeed in designing a car which will succeed in doing this, it will certainly deserve mention as a curiosity.

COMMERCIAL POINTS.

A MOTOR garage and repair department has been opened at Crown Hill, Croydon, by Mr. L. H. Turtle, under the management of Mr. F. G. Milne. A staff of qualified engineering mechanics and motor specialists is constantly on the premises, and Mr. Turtle advises us that he proposes executing all work, which will be of the best quality, at the lowest possible charge. A special scheme of "maintenance" and periodical reports is to be introduced, particulars of which are to be issued later.

DURING the manoeuvres of the French 5th Army Corps, which took place at Mirabeau, under General Duchene, the Minister of War occupied a seat in a 4-cylinder 12-h.p. Clement car, driven by M. Fenton. Prior to reaching the scene of the manoeuvres, the car (with the Minister of War as passenger) travelled long distances. In a single day M. Fenton, we learn, ran from Mirabeau to Troyes and Brienne for the great manoeuvres of the East, under General Brugère. M. Fenton states that his was the only car present to go through without a single "panne."

THE Petromobile Company, Limited, announce that they have taken over the business in all its branches, and the premises, carried on previously by the Locomobile Company of Great Britain, Limited, at 54, Sussex Place, South Kensington, S.W. In addition, the Company will have works at 45, Goldhawk Road, Shepherd's Bush, where the facilities for all repairs, both in connection with petrol and steam cars, ensure their being rapidly carried out.

SUCH a very large number of automobilists are also golfers, that it may interest many of our readers to learn that a golf scoring card has just been issued by Messrs. Humber, Limited. This card is supplied free to any golf club, with name, &c., printed at the head, by Messrs. Humber, Limited, of Beeston, Notts, upon application. The arrangement of the card is simple and comprehensive.

THE HON. STEPHEN COLERIDGE, who recently had such a very wordy passage of arms with the Andover road "banditti" and their superiors, has, we learn, just indulged in one of the new type 15-h.p. Orleans cars.

"Managed by a lady with ease" is the verdict of Mr. W. Watkins, of Peringa, Newport, Mon., in regard to his 9-h.p. Oldsmobile which he recently acquired, and which is seen in our photograph, with Miss Watkins at the wheel, about to start on a 60-miles run.

ANOTHER example of the nice sort of spirit that animates local authorities of the more provincial order, is provided by the case of the Folkestone Watch Committee, who, at its last meeting, solemnly listened to the following proposals put forward by the Chief Constable:—

"That local authorities should have power to fix the maximum rate of speed in towns and villages without reference to the Local Government Board; magistrates should have power to suspend or revoke licences to drive for any offence connected with the driving of a motor car, also in serious cases to revoke the registration of the car or to order the car to be impounded for a stated period, and to order the defendant to pay the cost of the car being stored; all convictions for offences relating to the driver of a motor car should be endorsed on the licence; the owner of the car should be compelled to give the name of the driver for any offence alleged, or when any accident to any person or animal has taken place; failing to do so should be an offence for which the owner may be proceeded against in the district where the alleged offence by the driver was committed or the accident occurred."

We are informed that the subject is to be further discussed by the whole body of the Council; probably it is just as well that the powers of this august body are limited to discussion.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.L.Mech.E., Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

24376. 10th November, 1904. Improvements in and relating to Clutch Mechanism. William G. Clifton, A.M.I.M.E., 35, Stavordale Road, Highbury, London, N. This invention relates to clutch mechanism which is more especially designed to be attached to and work in conjunction with a flywheel. The connection between the driving part and the driven part of the clutch is provided with means for varying the frictional resistance from a free drive, passing through various stages of slipping up to a positive drive. To obtain this variable resistance the clutch driver is provided with a number of cylinders, and the driven part with pistons movable in the cylinders, a liquid, such as oil, being circulated by the pistons. The resistance offered to this circulation of oil is determined by valves interposed, so that when the valves are fully open the driver revolves idly, and when the valves are fully closed the driven part revolves positively. Intermediate positions of the valves afford slipping between the driving and driven parts. There are two figures. Fig. 1, is a front elevation of the flywheel. The flywheel, *a*, is provided with a number of cylinders, *b*, which are integral with the flywheel, and extend radially inwards from the periphery thereof. They are furnished with passages communicating together through a valve or cock, *e*. Each cylinder, *b*, is provided with a piston, which by means of a piston rod, *g*, is secured to one end of a connecting rod, *h*.

The rods, *h*, at their other end, are mounted on a crank pin or crank pins, *i*, of a crank-shaft forming the clutch-shaft. This shaft is in line with, but separated from the flywheel shaft. Upon the shaft is loosely fitted a sliding collar, which by means of an arrangement of links or levers, opens and closes the valves, *e*, simultaneously. The cylinders, *b*, and passages are filled with this oil or other suitable liquid, which can be either circulated by means of the piston or serve to buffer the latter. As the flywheel or driver revolves (the driven shaft being stationary, and the valves, *e*, being open), the liquid is forced by the pistons in their reciprocating move-

ments through the passages and through the open cocks, *e*, from one end of the cylinder to the other. The crank pin, *i*, of the clutch-shaft being eccentric to the shaft of the pistons moves outwards in turn. When the valves, *e*, are closed the circulation of fluid is stopped, and the pressure of the fluid in each of the cylinders acts on its piston, and the latter by means of the rods, *g*, *h*, causes the crank pin, *i*, to rotate the clutch-shaft. The amount of slip in the clutch necessary when starting to drive the load or at other times is obtained by opening the valves, *e*, to the extent required.—September 27th, 1905.

25157. 10th November, 1904. Improvements in Two-Stroke Cycle Internal Combustion Engines. John W. Seal, 37, Westcroft Square, Hammersmith, London, W. This invention relates to internal combustion engines of the two-stroke cycle type, and has for its object an improved form of engine wherein the cylinder is self-scavenging, whilst the valve which conveys the charge from the compression chamber to the working cylinder serves to store the compressed charge, only admitting it to the working cylinder at the proper moment for operating in the latter. There are three figures or diagrams showing three different positions. Fig. 1 illustrates the cylinder and valve of this engine; *a* is the working cylinder, *b* the working piston having an enlarged diameter at *c* which constitutes the pump-piston. *d* the valve, *e* the principal exhaust port of the cylinder,

Fig. 1.

a subsidiary exhaust port, *g* the inlet port for the air combustible mixture, *h* a port in the cylinder wall communicating with the compression chamber, *i*, above the piston, *c*; *k* a slot or passage in the valve, *d* adapted to bring the port, *h*, into communication with the port, *g*; *l* the igniter or ignition chamber; *m* a port in the valve, *d*, adapted to communicate with the igniter; *n* the port leading into the working cylinder, *a*; *w*, water jackets; *p*, the piston pin. The valve, *d*, is operated from a cam or eccentric on the crank-shaft. The inlet for a jet of water, steam or the like at *s* and the non-return valve, *t*, in the valve, *d*, is adapted to communicate with the port, *s*,

in the topmost position of the valve. It is assumed that the piston, *b*, is making its working stroke with the gases coming from the interior of the valve, *d*, and reaching the cylinder, *a*, through the port, *n*. Simultaneously a charge of air, gas and air, or vapour and air is being drawn into the compression chamber, *i*, through the ports, *g* and *h*, and valve passage, *k*. As the piston, *b*, approaches the end of its stroke it uncovers the exhaust port, *e*, through which the gases escape. The valve, *d*, is descending, and has just cut off the opening for admission of gas through the port, *h*. Whilst the piston is at a dead centre the valve is moving downwardly rapidly, and by the time that the piston is at about half-position the gases from the compression chamber, *i*, are being passed through the passage, *h*, into the interior of the valve, *d*. Any gases that remain in the working cylinder, *a*, are being expelled through the port, *n*, and additional exhaust port, *f*. During the remainder of the in-stroke the valve, *d*, rises gradually, cutting off communication between its interior and the compression chamber, *i*, and also between the cylinder, *a*, and additional exhaust port, *f*, and finally just after the piston has reached the top of its stroke the port, *m*, comes into communication with the igniter, *l*, whereupon the compressed gases in the chamber of the valve, *d*, are ignited. The gases passing through the port, *n*, operate upon the working piston, and the working stroke ensues, whilst a fresh charge is drawn into the compression chamber, *i*, as before explained. In order to prevent overheating of the valve chamber and cylinder and to reduce danger of pre-ignition it is preferable to inject water or steam into the valve, *d*, at the end of the working stroke. For this purpose the port, *s*, is connected with a supply of steam or water under pressure, and the non-return valve, *t*, serves to allow the steam or water to enter the interior of the valve, *d*. The steam admitted or formed in the valve drives out the waste gases before it, and also cools the valve and cylinder.—September 27th, 1905.

The Immediate Success of the **REPAIR DEPARTMENT**

OF

A ARGYLLS, LONDON LTD.,

is due to the fact that the staff employed is composed of thoroughly skilled mechanics, trained at the Glasgow works, and transferred to Argylls, London, Ltd., for the purpose.

The Department has been fitted up and equipped with the sole view of effecting efficient and rapid repairs to all types of ARGYLL AND OTHER CARS at reasonable prices.

NOTE THE ADDRESS!

ARGYLLS, LONDON, LTD.,

17, Newman St., Oxford St., W.

The following is a list of ARGYLL Cars stocked at the above premises:—

A LICENCE, ITS ENDORSEMENT, AND OFFICIAL ACKNOWLEDGMENT OF A FALSE CONVICTION.—
Above we reproduce the driving licence of Mr. Frederic Coleman showing the original endorsement by the "justices" of the Borough of Colchester, of a conviction for "driving to the danger" of the public, which is now seen to be cancelled and underneath a permanent record of "error" on the part of the Borough "justices" substituted. We deal with this case elsewhere in the present issue.

THE AUTOMOTOR JOURNAL.

Telegraphic address: Truditur, London. Telephone: 1828 Gerrard.

SUBSCRIPTION RATES.

THE AUTOMOTOR JOURNAL will be forwarded, post free, to any part of the world at the following rates:—

PASSING EVENTS.

Another Aspect of the Traffic Problem.

WE referred last week to the discrepancy between the report of the technical advisers to the Royal Commission on London Traffic, and the recommendations which, not as a result, but in more or less flat contradiction of their advisers' suggestions, the "inexpert" members of the Commission have put forward. The absurdity of the situation has had one beneficial effect. It has awakened the general Press of the country in an even more marked degree than ever we remember before, to the absolute necessity of the problem being seriously tackled, and to the enormous loss which results to the trade and wage-earning capacity of the community as the result of defective traffic, and the manner in which even such traffic as exists is interfered with by the fantastic manipulation of our streets.

The three distinguished engineers who have been going into the subject fully and exhaustively, report that the wage-earning capacity of those employed in Greater London is upwards of 173 millions per annum. Needless to say, a large proportion of these people are employed in services which necessitate going from point to point, and it is worth employers' time to pay this immense sum for services, it is obvious that every time a road is up and 'buses are compelled to take one of the customary detours, the loss in value runs into enormous figures. Indeed it has been computed that the loss of a quarter

of an hour out of a working day of eight hours would mean on the total earning capacity of Greater London a loss of nearly six millions annually. This, at any rate, is the calculation of Sir J. Wolfe Barry and his colleagues in their report on the loss to the inhabitants of the Metropolis due to the lack of proper travelling facilities. The corollary from these estimates, of course, is that with the immense increase in rapidity of locomotion which the engineers to the Royal Commission on London Traffic have proved to characterise the motor vehicle, a corresponding increase in value to employers would result. This is only one of the many, and possibly not one even of the most important, results that will follow the universal adoption of the motor 'bus, but it is an important one, none the less, and it is worth noting.

A Splendid Piece of Work.

THE thanks of all automobilists are due, and will, no doubt, be accorded, to the Joint Committee of the A.C.G.B.I. and Motor Union for the splendid collection of data and statistics which have been collected, during recent months, for the information and assistance of the Royal Commission on Motor Traffic. The whole automobilist case has been collected and systematised, as the result of these labours, in the most comprehensive manner imaginable, and the cogency of the conclusions reached, which are supported by the most accurate and incontrovertible reasoning, has been confirmed by the compilation from first sources of returns dealing with practically all the main questions under dispute. Of these, needless to say, we can only mention a few, but as illustrations of the thorough way in which the work has been done, we would observe that returns have been obtained from thousands of doctors using motor cars for their professional work, from coroners relative to the comparative dangerlessness of the new locomotion, and statements of public men condemning the hard and fast speed limit, while, in addition, the effect of the automobile in increasing the value of property is illustrated by comprehensive returns from valuers and house agents. In fact, the labours of the Joint Committee, with its staff of enthusiastic clerks and assistants, who have often been working till 12 o'clock at night for weeks together during recent months, and Messrs. Mallam, Perrin and Sharpe, who have assisted the Committee in every possible way, have resulted in the compilation of as fine a case for a great movement and a great industry as ever was prepared for the assistance of a Government inquiry. When we say this we would desire to bestow a special meed of praise and recognition on the hard work and admirable management of Mr. Rees Jeffreys, who has been, from first to last, the guiding and, we may say, the inspiring spirit of the labours of the Joint Committee and those who have co-operated with them.

Poetic Justice.

THE inhabitants of Andover are beginning to have more than enough of their county magistrates, and the tactics which have led to the district attaining so unenviable a degree of notoriety in automobile circles. The Andover Road has, of course, become taboo. No motorist now proceeds along it except by accident or through having lost his way, for he knows that should he fall into the police trap on that road the speed at which he is proceeding is quite immaterial. He will be summoned however moderate it may be, and with equal certainty Colonel "Handover" Harmar and his

coadjutors will convict him. The result is that Andover, which was once alive with motorists, is now almost deserted, and the traffic and business which once was brought to it, is now deflected to other towns like Whitchurch and Basingstoke. To what an extent the "legalised brigandage" of Andover has affected the traffic in that magisterial preserve, may best be gathered from the fact that in place of many hundreds of cars which passed there weekly, almost daily, during the whole of Saturday last *four only passed*, and on Sunday *five only*, while needless to say that with the A. A. Scouts "out" in the district, the traps bristling with "Hedgehogs" were at a discount. Needless to say the Andover tradespeople and hotel-keepers have suffered considerably, and are now adopting towards the Andover Bench an attitude very similar to that which the Reigate townspeople took up towards the Reigate Bench when that august body pursued similar tactics. Matters are made worse for the townspeople by the fact that the officers at Tidworth Barracks and on Salisbury Plain have adopted the same attitude as motorists, and have refused to come near the town. The feeling of the townspeople has been embodied by a prominent Town Councillor, Mr. H. C. Hammans, who disowns all connection between the magistrates (and the police, who are controlled by the county authorities) and the town. Councillor Hammans is a brewer, and no doubt he finds that the consumption of fine ales has been considerably diminished by the "Handover" tactics of the county Bench, while another prominent tradesman of the town declares that if a poll of the townspeople of Andover were taken 99 per cent. of them would demand more rational treatment for motorists. It is the usual story. A body of irresponsible and narrowminded crotchety magistrates, interfering not only with the enjoyment of other people with whom they do not sympathise, but with the business and prosperity of a whole neighbourhood, out of sheer prejudice and dislike of a new development.

The following is a further practical illustration of the effect this "administration" of justice is having on the district. Mr. A. Halstead, in writing upon the subject to the *Andover Advertiser*, has published the following letter which he received from Sir Charles McLaren, Bart., in response to an application on behalf of a movement to benefit the working men of Andover:—

"In reply to your letter, I may say the only thing I know of Andover is the legalised brigandage organised by your magistrates for the plundering of motorists near your town.

"Being an advocate of fair play and common sense, I will have nothing to do with Andover under the present conditions.

CHARLES McLAREN.

"43, Belgrave Square."

"Danger to the Public" Must be Proven.

At the end of August last, Mr. Frederic Coleman was charged before Essex magistrates with having driven to the public danger at Lexden. He was defended by Lord Russell, and the case presented some amusing features, particularly, as usual, in regard to the police evidence, the constable who stopped Mr. Coleman refusing to admit in the witness-box what he had said on the road, that there was no danger to anybody, and when asked if he thought there was any danger, observed that it was "not for him to think," though he finally, reluctantly, admitted that the car was pulled up, even at the speed at which it was going, in a distance of about thirty feet. In spite of the evidence, however, even of

the police, which ought to have secured, one would have thought, a dismissal of the case, the Bench convicted Mr. Coleman, though they only fined him 40s. and 13s. costs. Lord Russell gave notice of appeal, and this appeal has now been heard at Colchester, with the result that the conviction has been quashed, Mr. Coleman awarded full costs, and his licence re-endorsed with a revocation of the previous conviction. Now this is a very important decision, the ground on which the Quarter Sessions Court arrived at it being that where danger to the public is asserted, under Section I. of the Act, that danger must be proved, and the result is emphasised by the circumstance that the Court was presided over by the trained legal intelligence of the Recorder. This is important, first of all because it adds one more to the long list of Quarter Sessions decisions in which this point has been maintained. In fact, it is scarcely too much now to say that it is a point which is universally recognised by Quarter Sessions Courts. In the second place, Mr. Coleman was awarded costs, a point of almost as much importance as the reversal of the original magisterial decision. Petty Sessional Magistrates do not like to have their decisions reversed in any case, but if they are reversed without the appellant receiving costs their equanimity remains comparatively unruffled. The award of costs produces more effect on their minds (if any) than any number of adverse decisions without costs will do. We hope the precedent of Colchester, therefore, will be generally followed. In that case, we may look forward to magistrates being more careful in the decisions they give on the question of driving to the public danger in the future.

A Hoary Canard.

SOME time ago we gave currency to a statement to the effect that in 1904 motorists had been deprived in fines, by the combined machinations of magistrates and police throughout the county, of the substantial little sum of £218,000. As we found the statement in an official publication, *i.e.*, the club Journal, we had no hesitation in giving it further currency in our columns. In due time the *canard* in question, after fluttering through the Press for the proverbial period of nine days, was at length laid to rest. Now, some months afterwards, it has been dug up by an enterprising contemporary, and started on a new flight in, it must be admitted a somewhat "gamey" condition. The explanation of the whole thing is now forthcoming—£218,475 was the precise amount of fines inflicted by Courts of Summary Jurisdiction throughout the kingdom during the year 1903, as stated by Mr. Akers Douglas, in reply to a question in the House of Commons. Of this sum, £144,258 went to county borough and police funds, £42,886 to the police, £5,628 to the Exchequer, and £25,703 to other persons. It is probable, no doubt, that motorists contributed considerably to this amount, but they certainly did not contribute the whole of it, and the people who have been arguing from the huge amount, on the one hand how bad motorists must be, and on the other hand what shocking depredators Justices of the Peace are, must revise their views of the situation—and also alter the year to which the figures apply. We are sorry for them. We must admit having assisted the *canard* upon its flight, though, as above explained, we did so in the best of good faith and implicit belief in the reliability of the information.

For the General Good.

THE London County Council has, it is announced, decided to apply to the Board of Trade for permission to increase the speed of its trams, at any rate in certain cases, from the present legal limit (seldom observed, by the way) of 10 miles an hour to 16 miles an hour. Everyone who has the improvement of London traffic and the means of communication at heart, will be in favour of the proposed concession. One of the chief objections to the electric tram as at present constituted is the manner in which it delays other traffic, and that effect is likely to be diminished by extending its limits of speed. It is mainly, however, as a matter of principle that we are in favour of the suggested concession, for in point of fact (as has been proved over and over again), the tram drivers, in the South of London at any rate, pay no more attention to their legal speed-limit than a Bench of Irish magistrates do to the law, so that it is only exceptionally that much effect on the general traffic will be noted. If the Board of Trade, however, agree to allow the legal limit of tram speed in the metropolis to be raised, we think in common justice, and in accordance with the sacred principle that what is sauce for the goose should be sauce for the gander, that the Local Government Board should permit a similar extension of the speed limit in the case of motor 'buses. At present, as the result of the Board's ordinances, their speed is limited to 12 miles an hour. Notwithstanding this disability, however, they have shown themselves, to the satisfaction of the Commission of Engineers who have reported recently on London traffic, to be the fastest public conveyances on the London streets. It would be a gross injustice if, while relief is given to the electric tram, the motor 'bus should be thus unfairly and unjustifiably handicapped.

A Matter for Opposition.

WHILE we approve of the County Council's action in the above respect, we feel called upon to most wholeheartedly condemn their action in another direction. If there is one district in London which the motor 'bus has made pre-eminently its own, that is the neighbourhood served by the Edgware Road as far as Cricklewood. This line has in the past been very inefficiently served with 'buses. The coming of the motor 'bus has revolutionised traffic along the whole distance, and the motor 'buses are now beginning to deal most satisfactorily with the traffic, and proving a thorough boon to the inhabitants. Will it be believed, therefore, that the London County Council are promoting a bill to empower them to lay electric tramlines along the Edgware Road from Marble Arch to Cricklewood. It is evident that the County Council does not like the motor 'bus. Doubtless it recognises it as the most dangerous competitor of its own electric trams. Needless to say, if the County Council obtain these powers, the entire traffic will be disorganised throughout the long period while the trams are being laid (when the usual unspeakable chaos will prevail) and seriously handicapped subsequently, not by the fair competition of the trams so much as by being impeded in their movements by these inflexible encumbrances of the highroad. It cannot be urged that the tram extension is needed. In fact the whole proposition has the appearance of a deliberate attack on the motor 'bus by a municipality which, for reasons not necessarily connected with the public welfare, is wedded to the electric tram.

HIGH-TENSION MAGNETO IGNITION.—PART XIII.

BASSÉE-MICHEL SYSTEM (1906 MODEL)— AN ENTIRELY NEW DESIGN.

Introduction.

IN every respect this new model—for which Messrs. Gauthier and Co. now have the English agency—differs from that which Messrs. Bassée-Michel introduced last year. It is different both in principle and design, for not only have the manufacturers adopted a separate induction-coil—originally peculiar to the Eisemann system—but they have discarded their circular magnets in favour of the more orthodox horse-shoe type. The 1906 Bassée-Michel magneto is, therefore, an entirely new machine. It is still distinctive in appearance, and it still reflects in its construction that same ingenuity and careful attention to detail which characterised the previous model.

More important, however, is the fact that the manufacturers have evolved a new system of wiring which is quite different to everything which has hitherto come before our notice—in fact, its chief advantages were discovered more or less accidentally. Briefly stated, the

facturers to result from this system. One is that it is impossible to “burn out” the armature, no matter how fast the magneto may be driven; the other is that the same machine gives a much better spark when used in this way than it does when used on an ordinary induction-coil having but one primary winding.

The general principles on which any high tension spark is produced are already familiar to readers of our introductory chapters on this subject, and as the explanation we then gave applies in this case also, it is not necessary to deal at great length with the theory of the system. It will be remembered that we then pointed out how a spark could be produced at the instant of *making* the primary circuit instead of at the instant of *breaking* it, if the initial voltage were sufficiently high; but that it was more usual to employ the latter method on account of the increased facility with which it brings about a rapid change in the strength of the magnetic field. The Bassée-Michel system is, in a sense, a combination of both principles, for the interruption of the current in one coil brings about

FIG. 1.—The Bassée-Michel High-Tension Magneto (1906 Type).—View of the complete machine, together with the separate Induction-coil, which has two primary windings. The use of these two windings is a special feature of the Bassée-Michel system; one of them being of comparatively low resistance, the same coil can be used with accumulators when necessary.

innovation consists of employing two primary windings on the induction coil—originally one for the magneto and the other for the auxiliary battery ignition. These windings have different resistances, and one end of both is connected to the magneto, so that they are in “parallel.” The other end of the coil, having the greater resistance, is connected to “earth,” and it thus permanently closes the armature circuit. The corresponding end of the other coil (the battery coil) is connected to the contact-breaker in such a way that it is dependent upon the *closing* of the contacts for the completion of its circuit with the armature coil. So long as the contact-breaker is closed, therefore, the armature can force electricity through both primary windings, and even when the contact-breaker is open, it is still able to keep some of its current flowing through one of them.

Two advantages are especially claimed by the manu-

an increase of the current in the other, and it is this sudden change which produces the phenomena culminating in a spark at the ignition plugs. It is, as we have explained before, the suddenness of the change which determines the intensity of the spark. In this system the current in the unbroken primary coil is given an impetus when it is already in full swing, and, judging by results, this appears to be a very effective method of producing a rapid change in the magnetic field. It is possible, however, that this may not be entirely accountable for the successful working of the scheme, but there is insufficient data available at this early stage of its development for any more detailed analysis of the theory to be made at present. An outcome of this system is that it enables a set of accumulators to be employed without the necessity of providing a separate coil more suited to their voltage than is that usually employed with magnetos.

The primary winding of least resistance in the Bassée-Michel coil is specially constructed to be suitable for use with accumulators, and a special switch is provided by which they can be instantly substituted for the magneto when required. The high-resistance primary coil is in this case cut out of action, but as there is no trembler, the contact-breaker—which is mounted on the magneto—is still made use of, as is also, of course, the distributor for the high-tension current.

In construction, the machine does not differ greatly from other magnetos, but great attention has been paid to accessibility, and the apparatus is very easy to dismantle. There are, too, remarkably few screws employed for securing parts which may be required to be easily removed, and the very ingenious application of slotted washers and springs, employed on what is virtually the bayonet-socket principle, has, in certain cases, formed an admirable solution to the difficulty of providing a readily removable but efficient fastening.

Our Illustrations.

A view of the complete machine, together with the separate induction-coil, is shown in Fig. 1. Some of the more important component parts are illustrated in Fig. 2,

The Magnets.

The magnets are of the ordinary "horse-shoe" type, but they are made up of no less than ten elements—which is an unusually large number for compound magnets of this size. A flat brass bed-plate, G^1 , supports them, and affords a base by which the machine may be secured to the car. The pole-pieces are, as usual, made of cast iron, but they are somewhat longer than the magnets themselves, and they overlap at one end. This, however, is merely for constructional purposes, and is not in any way dictated by the theory of the machine.

The Armature.

There is no appreciable difference between this and other armatures in magnetos of the *low-tension* type. The core, A, is built up from numerous thin sheets of soft iron, which are insulated from one another by varnish, and the whole is mounted between two brass end-plates, B^2 , which carry the halves, B, B^1 , of the armature-spindle. Over the core is wound the coil of wire in which the electricity is generated; one end of this coil is "earthed" to the core, but the other passes through an insulated bush in one of the brass end-plates and is connected to the brass "slip-ring," C^1 , which is visible in

FIG. 2.—The Bassée-Michel High-Tension Magneto (1906 Type).—Views showing the more important parts arranged in their relative positions. The method in which the Distributor is driven from the Armature Spindle, and the position of the Collector Brush, C^1 , are prominent in this illustration.

where they are arranged in their relative positions, and views showing the more interesting details are given in Figs. 3, 4, and 5. We have also prepared three separate diagrams in order to make the electrical connections of this system thoroughly clear. The first of these, Fig. 6, corresponds in general appearance and arrangement with those which have appeared previously in connection with our descriptions of other systems, and will therefore enable this system to be readily compared with them. Then there is the diagram of wiring, Fig. 7, which gives graphically all the necessary information to enable the magneto to be connected up when installed on a car. And in addition to this, there is another diagram, Fig. 8, which is, to a certain extent, a combination of both Figs. 6 and 7, and may, perhaps, enable some of our readers to more readily grasp the system, since the way in which the coils are arranged separately in this illustration enables the various circuits to be followed more easily. It must, of course, be understood that the three coils are, actually, wound over one iron core, as they are diagrammatically shown in Fig. 6. An important detail of the apparatus is the special switch which is illustrated in Fig. 9.

Fig 3. This brass "slip-ring" is, of course, carefully insulated from the brass end-plate on which it is mounted.

Both ends of the armature-spindle are carried in the ball-bearings provided in the bearing-plates, M and M^1 , which are screwed up against the magnets. The bearing-plate, M, supporting the driving end, B, of the armature-spindle, is used solely for this particular purpose, but that at the front end of the machine also carries the contact-breaking and distributing mechanisms. The armature is driven, in the usual way, from the engine by means of a spur-wheel, or chain sprocket, fixed on to the end of the spindle, B. In practice the magneto is usually driven at the same speed as the crank-shaft.

(To be continued.)

Pure Speed Racing versus Tourist Car Tests.—This important question, which is now agitating the various leading automobile bodies throughout the world, is the question on which a serious split has taken place in the Milan A.C., leading to the resignation of the president, the Chevalier Massoni, and the members of the committee.

THE 1905 ARGYLL CARS.—PART III.

(Continued from page 1295.)

The Standard Engines.

To a certain extent, the Aster engines, which are now to be built in the Argyll works also—as recently announced in our columns—but more especially the 24-h.p. Argyll engine, now demand our attention. Its four cylinders, each of which are formed by a separate casting, have a bore of 95 mm., and the stroke is 130 mm. It is thoroughly up-to-date in design, possessing as it does most of those features which modern practice has shown to be so valuable. The nickel-steel crank-shaft, for instance, is supported by bearings between each crank, and these are arranged in such a way that the base of the crank-chamber can be taken off without disturbing the crank-shaft. The cam-shaft, moreover, can be drawn out longitudinally, it having the sleeves that form its bearings larger than the cams; the sleeves come out with

requires no stuffing-box, the end-thrust of the revolving member being ingeniously utilised for making a water-tight joint between that member and the external casing. For keeping the water cool in the honeycomb radiator, a belt-driven fan is fitted to the engine immediately behind the radiator. The normal engine speed is the same as that of the Aster engines, viz., 1,100 revs. per min., and the form of carburettor usually fitted is of the Longuemare type, with an automatic valve for admitting auxiliary air. In certain cases, however, other carburettors are employed instead.

Of the Aster engines, comparatively little need be said in this article, for they are already well known to most of our readers, and their many excellent features are very generally recognised. Certain models have separate cylinders and others have the cylinders cast in pairs.

The 10-12-h.p. Argyll Car, fitted with tonneau body; this is the only Argyll model that has a two-cylinder—instead of a four-cylinder engine.

the shaft, and the cams can therefore pass through the end of the crank-chamber. A high-tension magneto is fitted, as well as a commutator, for the battery ignition, both being gear-driven, and there is also a centrifugal governor which automatically controls the speed by acting on the throttle-valve.

All the valve-lifters have small rollers to reduce the wear of the cams, and everything has been done to render the engine silent. An interesting detail is the manner in which the gudgeon-pins are held in place in the pistons, this being done by the simple expedient of fitting a fourth piston-ring so that it passes around the ends of the gudgeon. All the gearing is enclosed in the crank-chamber, the commutator is placed in a very accessible position, and the induction-pipe renders each inlet-valve equidistant from the carburettor. The circulating-pump, which is of the centrifugal type and is gear-driven, is specially noticeable in consequence of the fact that it

As fitted to Argyll chassis, magnetos can be added if desired, but under ordinary circumstances battery ignition is alone supplied. The 26-30-h.p. engine has a bore of 105 mm. with a stroke of 140 mm., and the corresponding dimensions of the other engines are as follows: 16-20-h.p., 88 mm. by 130 mm.; 12-14-h.p., 84 mm. by 110 mm.; 10-12-h.p., 95 mm. by 140 mm. The last-mentioned is a twin-cylinder model, but all the others have four cylinders; it is seen in place—from the inlet-valve side—on a chassis, in Fig. 13.

The Clutch.

Except on the 10-12-h.p. models, the clutches used on all Argyll cars are of the Hele-Shaw type, with which our readers are already more or less familiar. It will be remembered that this clutch belongs to that variety in which a number of thin metal discs—alternately carried by the driving member and the driven member—are forced up

Fig. 13.—View of the twin-cylinder engine, fitted in place in the 10-12-h.p. Argyll Car; in this illustration the ignition-plugs, which lie above the mechanically-operated inlet-valves, are prominent.

against one another in an oil bath by the clutch-springs, and are allowed to separate when the clutch-pedal is depressed. The special merits of such clutches are that they tend to come into operation without any kind of shock, that the oil allows them to "slip" when such action is desired, and that they will continue to work for a long period of time without requiring any adjustment or other renewal than the lubricant. These and other general matters relating to their use were entered into very fully by us when describing the Bradley clutch (on March 11th and 18th last), and need not therefore be repeated now. The distinctive features of the Hele-Shaw model are, however, that the discs are corrugated instead of being quite flat, and that they are separated by small springs instead of by a more positive mechanism.

The precise form in which the clutch is employed by the Argyll Company is illustrated in Figs. 14, 15, 16, and 17, which show it fixed in place in a 4-cylinder chassis, show it dismantled sufficiently to expose the interior, show one "driving" ring and one "driven" ring separately, and give a transverse section through the entire mechanism, respectively. The clutch occupies the whole available space within the fly-wheel, and the operating-mechanism by which the discs are caused to disengage with one another is of a particularly substantial character.

Referring to Figs. 15 and 17 (especially the latter), it will be seen that the hollow fly-wheel, H, is bolted to a self-registering flange on the engine crank-shaft, and that it has a number of "driving" guide-pins, H¹, projecting inside it, parallel with the axis of the shaft. The pins, H¹, form guides for the "driving" discs, H³, which are correspondingly slotted around their periphery for this purpose. Also passing through slots in the outer edge of the discs, H³, are three equidistant pins, H², but these are fitted in such a way that they can be screwed in or out further in relationship to the fly-wheel, and

enable the three clutch-springs, H⁴, to be adjusted—as we shall now proceed to show. The pins, H², are provided with small, circular spring-casings, H⁵, having shoulders at each end, the one shoulder projecting outwards in order to engage with the three-armed spider, H⁶, and the other shoulder projecting inwards for the spring, H⁴, to thrust up against. The springs are held up against the inner shoulders by nuts on the ends of the adjustable pins, H², and they therefore tend to force the spider, H⁶, inwards—towards the discs, H³—with a pressure that can be varied by screwing the pins, H², in or out. The three-armed spider, H⁶, is, in turn, controlled by the clutch-pedal (J⁶), for it is mounted freely about the "driven" shaft, J, and has a collar for the ball thrust-bearing, H⁸, of the clutch-fork mechanism, H⁹.

The "driven" member consists of the externally-toothed casting, J¹, and of the discs, J², which are so slotted as to engage with the teeth on that casting.

The discs, J²—like those on the driving pins, H¹—are free to slide towards or away from one another, but both

Fig. 14.—The central portion of a four-cylinder Argyll Chassis, showing the multiple-disc clutch, and the "Govan" change-speed-gear, with its operating mechanism.

Fig. 15.—View of the multiple-disc clutch employed on all four-cylinder Argyll Cars; in this illustration the oil-tight cover (H⁷), and one of the clutch-springs (H⁴), have been removed, and are shown separately.

sets are compelled to revolve with their respective clutch-members. They project alternately between the discs, H³, and their V-shaped corrugations fit into those of the other discs. Normally, the discs are all prevented from pressing up tightly against one another by flat springs riveted to the discs, H³—as seen in Fig. 16—but these flat springs do not prevent the discs from being forced

together by the three helical springs, H⁴. At its front end, the clutch-shaft has a spigot supported by a ball-bearing in the fly-wheel, H, and, just inside the coupling-flange at the other end, it has another ball-bearing in the bracket, J³. The casting, J¹, rides upon a square portion of the shaft, J, and is, therefore, capable of accommodating itself to the discs. To render the bracket, J³, rigid with the frame, it is braced to the gear-box by the stay, J⁵.

Other points of interest about this clutch are that a brake-flange, J⁴, is fitted to the shaft, J, and that provision is made for filling the fly-wheel with fresh lubricant and draining off what was left. The mechanism, H⁹—which is connected with the clutch-pedal, J⁶—has a corresponding brake-member that comes in contact with the revolving flange, J⁴, if the pedal is fully depressed, and thus the “driven” member of the clutch can be slowed

up quickly, when necessary, for changing gear. For introducing the special lubricant into the oil-tight casing, formed by the fly-wheel, H, and the cover, H⁷ (which has inspection plugs for removing the clutch-springs), there are four screw-caps in the periphery of the wheel; they enable it to be filled exactly to the correct level—just upon half full.

Fig. 16.—A “driving” disc (H³) and “driven” disc (J²), several of which are employed in the special clutch used on all four-cylinder Argyll Cars.

Fig. 17.—Sectional drawing, showing the construction of the multiple-disc clutch, adopted by the Argyll Company.

MR. GEORGE BURTON, a Preston motorist, enjoyed the unique experience, on Sunday last, of careering at 40 miles an hour through the streets of Burnley, aided and abetted and actively assisted by the police, who kept the public as far as possible off the roads to facilitate his progress. A fire engine had broken down on the way to a cotton factory which was on fire, and Mr. Burton was carrying, as fast as he could, a cargo of firemen with some equipment to the scene of the conflagration.

A few words should also be said about the other form of clutch—that fitted to the 10-12-h.p. car—for even though it is of a more usual type, it differs from others of the internal leather-faced cone variety. The inner member is normally pressed *outwards* by the clutch-spring against the corresponding conical face of an outer ring, but the special feature to which we are directing attention is that this outer ring can be adjusted—relatively to the fly-wheel—by three nuts. A further adjustment for taking up any wear of the leather is thus rendered available.

(To be concluded.)

WE are glad to be able to chronicle the case of one Rural District Council, at any rate—that of Tendring—into whose minds somewhat more progressive notions seem to be penetrating. The Council is considering the idea that they ought to participate in the income derived from motor traffic, and, at the same time, think that this income should be distributed over the whole of the county, and *mainly used in the improvement and maintenance of roads.*

THE "M AND B" STEERING-GEAR.

OF the really important parts of a motor car, the steering-gear must undoubtedly rank among those of first consideration on account of the danger to life which may be caused by its failure. Simplicity and strength have, on the whole, been the leading features of the design of most gears, but in comparatively few cases has any form of adjustment been provided other than that necessary to take up the backlash of the steering-column itself. To compensate for the backlash in the intermeshing teeth of the gear is generally no very easy matter on account of the uneven wear which takes place between them. In gears of the worm and sector type, for instance, more wear will take place in the centre of the sector than at the ends because the car will more often be travelling straight ahead than turning corners. In taking up the

utilised for steering the car, and as it is possible in the arrangement adopted to always keep the same faces of the screw-threads in contact, no matter which way the bolt or nut may be moving, all backlash can be entirely neutralised, however much clearance there may be in the threads. Owing to the fact that, when in the straight-ahead position, the screw-threads are engaged almost throughout their length, the wear takes place uniformly and thus removes the danger to jamb which results from an adjustment compensating only for purely local wear. Referring to the illustration, this shows, on the left, a view of the gear complete, while, to the right, are several views of the gear in various stages of dismantlement, which indicate both its construction and the manner in which it operates.

The "M and B" Steering Gear.—View showing the gear complete (on the left), and its component parts separately, and also partly assembled.

backlash at the centre the gear would therefore be liable to jamb when the front wheels are given the full lock, and it is for this reason, it will be remembered, that the sector on the Wilson Pilcher car is originally made with some little backlash at each end so that it may actually improve generally as the wear is gradually taken up in the centre.

A form of steering-gear which is particularly interesting is that which is made by the well-known French firm, Malicet and Blin. This gear, which is illustrated above, from the model lent to us by Messrs. Gauthier and Co., has been designed more particularly for heavy cars which require a very substantial steering mechanism. The principal feature of interest, however, lies in the fact that practically no uneven wear can take place, and that one simple adjustment simultaneously takes up all backlash, whether the wear has taken place in the steering-column, or in the intermeshing threads of the gear.

The Malicet and Blin steering-gear is in principle a modification of the screw and nut gear used on some cars. The lower end of the steering column is rigidly connected to a sleeve which has a left-handed screw-thread on the inside and a right-handed screw-thread on the outside. A bolt and a nut, respectively, engage with these threads, so that, when the steering-wheel is turned, one of them moves downwards while the other moves upwards. The motion of the bolt and nut is

Although, perhaps, the variety of views shown in the illustration may give the idea of complication, this gear is nevertheless very simple, both in action and construction, while the general design is such that it may be quickly taken to pieces and re-assembled. The lower end of the steering column is connected to the phosphor bronze rod, A, which has, solid with it, an enlarged hollow end, A¹, forming a long sleeve. Both on the inside and the outside of this sleeve is a double screw-thread of square section, that on the inside being left-handed, and that on the outside, A², right-handed. Engaging with the inner thread is a steel bolt, B, and with the outer thread a steel nut, C; both these members are formed with a kind of foot indicated by the letters, B¹ and C¹, respectively. When in position these feet rest on two crank-pins, D¹ and D², which are arranged, as shown in the illustration, on the crank-shaft, D, and are fitted with loose sleeves to reduce friction. The crank-shaft, D, which is fitted with brasses, D³, is carried by bearings in the dust-proof casing, E and E¹.

The upper part, E², of the casing is cylindrical and receives the screw gear, A, B, and C, which is a sliding fit in it, the nut, C, being machined on the outside for this purpose. In order to ensure that the feet, B¹ and C¹, shall rest firmly on their respective crank-pins, D¹ and D², the casting, E², has a cap, E³, which screws down upon a ball-thrust bearing, A², resting

against a collar on the member, A. The whole gear may thus be quickly adjusted, and afterwards locked by the nut, E⁴. When the steering wheel is turned to the right, the left and right hand threads on the member, A¹, cause the bolt, B, and nut, C, to move downwards and upwards respectively, so that their feet, B¹ and C¹, cause the crank-shaft, D, to rock about its axis. One end of the crank-shaft carries the lever arm, which is connected to the steering knuckles in the usual way.

It will be noticed that, after the cap, C³, has been adjusted, the lower faces of the threads on the member, A², and the upper faces of the threads on the members, B and C, are forced into contact and, as it is impossible for either of the members, B or C, to move in one direction without a corresponding motion of the other in the opposite direction, these faces must therefore

always remain in contact whichever way the steering-wheel is turned. Any motion of the steering-wheel to the right acts through the pressure of the foot, B¹, and conversely all motion of the steering-wheel in the other direction acts through the pressure of the foot, C¹.

Table of Reference Letters for the Malicet and Blin Steering Gear.

A	Shaft inside steering pillar.	D ¹	Crank for B ¹ .
A ¹	Enlarged part of A.	D ²	Crank for C ¹ .
A ²	Ball thrust bearing.	D ³	Bearing brasses for D.
A ³	Screw on outside of A ¹ .		Dust-proof casing.
B	Inner threaded member.		Base for same.
B ¹	Foot on B.		Upper portion of E.
C	Outer threaded member.		Adjustable screw cap.
C ¹	Foot on C.		Lock-nut for same.
D	Crank-shaft.		

THE VIEO WHEEL.

Two views showing the cars on which Mr. Stuart Ogilvie has tested the "Vieo" wheel. That on the left is a 24-h.p. Napier. The other car is a 6½-h.p. Gladiator.

ALTHOUGH only just introduced to the public, this interesting device—the invention of Mr. Stuart Ogilvie—has already had an extensive trial on touring cars, two of which we are able to illustrate this week. One of these, on the left, is a 24-h.p. Napier, weighing, with its specially-designed body, about 2½ tons. It was on this car that most of the experimental runs, extending over more than 4,000 miles, were made, although the wheels were also successfully tried on the small 6½-h.p. Gladiator seen to the right of our illustration.

The interior arrangement of the present wheel is well shown in our other photograph, and the parts, which we were only able to illustrate by line drawings in our issue of July 1st, are rendered more clearly visible. The rubber rollers, which are interposed between the inner and outer members, form the resilient portion of the wheel, but the drive is transmitted through the four carriers and stops which are fixed to the two members.

The standard design, now in preparation, will embody some slight modifications in the design, and we therefore refrain from giving, at the present time, the more fully illustrated description which will form the subject of a future article in these columns.

View showing the interior of the "Vieo" resilient wheel.

THE GILLESPIE AEROPLANE.

WE have referred recently to several airships and aeroplanes which have executed actual flight of some sort. As an example of the direction which the minds of designers are taking, we now reproduce some photographs of a machine which has recently

aluminium and are 4 ft. in diameter, and it has been calculated that the machine should have a lifting power, at the speed it is capable of developing, considerably in excess of the dead weight to be carried. The motor itself has horizontal cylinders arranged in groups, the

GILLESPIE AEROPLANE.—The upper illustration shows the Gillespie Aeroplane from below, and as it should appear in actual flight, showing clearly the arrangement of the propellers and the structure and method of support of the forward lifting rudders. Below is another view showing the Aeroplane on the ground.

been designed in the United States — the Gillespie aeroplane. This machine, as will be observed, is of the perfectly flat type with 7 equi-distant propellers, driven by a petrol motor situated in a cage beneath them, in which it is intended that the aeronaut should recline in a horizontal position. It is also provided with bicycle wheels to enable it to get up sufficient speed on the ground to rise in the air, and presumably for use when it again descends. The propellers are made of

bore and stroke of each of the cylinders being 3 ins. by $3\frac{1}{4}$ ins. The cylinders are air-cooled, being wrapped with light wire spirals to act as a radiator, something like those of the Clarkson cooler, and high-tension ignition with a special commutator and dry cells is employed. The total weight of the motor is said to be 237 lbs., or a little over 10 lbs. to the h.p., as it develops about 20 h.p. The movements of the aeroplane are controlled by the moveable planes at either end. The framework

GILLESPIE AEROPLANE.—In the upper illustration is seen the Aeroplane from the near side and from below. The arrangement of the propellers and front and rear rudders may be clearly observed. The lower illustration shows the machine with horizontal motor and aluminium controlling wheel directly in front of the operator.

of the whole is constructed of aluminium tubing reinforced by piano wire, and the lifting surfaces themselves are formed of light duck stretched over the tubing. Its total lifting surface is some 200 square feet. We await

with interest further information as to whether this aeroplane is likely to take its place among the ranks of those machines which have actually succeeded in flying.

"Foot-pounds" and "Horse-power."—Writing in reference to our recent articles on the Tourist Trophy Race Question, a correspondent has asked us to explain the difference between the "pull in foot-pounds" and the "horse-power" of an engine. Realising that others of our readers may also experience a similar difficulty in grasping this point, we give the following brief explanation, which really resolves itself into pointing out the difference that there is between "work" and "power," since "foot-pounds" expresses the *amount* of work that is done, and "horse-power" expresses the *rate* at which that work is being performed. Assuming, for instance,

that an engine were to be employed for lifting a weight of say 33,000 lbs. up vertically to a height of 100 ft., then the "work" to be done might be expressed as 3,300,000 *foot-lbs.*, whether the engine were to take one minute or one hundred minutes in performing its task. If, however, one minute only were spent, then the power would be expended at the rate of 3,300,000 foot-pounds *per minute*, and the engine would therefore be giving 100 h.p., whereas if it took a hundred minutes, the power would be exerted at the rate of 33,000 foot-pounds per minute, and the engine would be giving 1 h.p.

THE LEYLAND-CROSSLEY 'BUS.

Our illustration, Fig. 1, shows one of these omnibuses, which has been in regular service between the Law Courts and Cricklewood, and Figs. 2 and 3 show the 'bus chassis from above and the side respectively. The propeller-shaft driving the live-rear-axle is enclosed in a stationary casing, which is mounted in a spherical bearing at its forward end, the bracket carrying the bearing being attached to the front of the chassis. The propeller-shaft is connected to the live-rear-axle by a universal joint, the propeller-shaft being supported by a bracket at its rear end, which is attached to the live-rear-axle.

Fig. 2.—The Leyland-Crossley 'Bus. View from above of the chassis, showing the live-axle with the stationary tube, enclosing the propeller-shaft, which anchors the axle to the frame.

Fig. 3.—The Leyland-Crossley 'Bus. View of the chassis, from the side, showing the suspension of the back-axle on the semi-elliptic springs which are shackled at the rear to a transverse spring, and rest in slides in front.

RACES, RECORDS, AND TRIALS.

At the same time we were disappointed, and we, therefore, took the first opportunity to discuss the matter with Mr. Earp—who drove the car this year—immediately upon his return. Mr. Earp is absolutely convinced that his car was never running better—and considering his experiences with this vehicle, and his recent victories at Dourdan and Chateau Thierry—he at least should be an excellent judge of its condition. Last year the actual speed of the car was over 76 m.p.h., but this year a new back axle was fitted in order to give a more suitable ratio, and the car was, at the time of the race, geared to 84 m.p.h.

Prior to the event, Mr. Earp made about thirty runs up the hill, and he estimates his *average* time for the flying kilom. on these trials as being $28\frac{1}{2}$ secs. = 79.3 m.p.h. If all went well he hoped to even better this time in the actual race. And in the event everything, so far as the car was concerned, did go well, even the elements were propitious, for the rain had put the roads into a slightly slippery condition, which made it easier to start this powerful two-speed car quickly.

In common with all sportsmen, we should naturally have been pleased had Mr. Earp followed up his previous successes at Dourdan and Chateau Thierry by winning the Gaillon Hill Climb, but the loss of personal victory is a smaller misfortune than the lost opportunity of establishing a new record on this hill, which has for so long been the scene of a classic contest.

No doubt this fact is equally unsatisfactory to the French, and as Mr. Earp is so satisfied that he was travelling, on that occasion, faster than he had ever travelled before, we cannot help thinking that there may, by some possibility, have been an error in the timing. We should, therefore, like to see—in order to put the question of the capabilities of the car beyond question—another meeting arranged under the auspices of the A.C.F., between Baron de Caters, Mr. Earp, and Messrs. Barras and Rigolly, and with, say, M. Tampier or some one of similar experience, as time-keeper. Messrs. Barras and Rigolly are still joint holders of the record (29 secs.) which they established last year and which by the timing this year was in nowise approached, and this very fact of a tie must in itself appeal to all as another important reason why an early opportunity should be forthcoming of allowing a new official record to be attempted on this famous hill.

INDIAN MOTOR TRIALS.—The Aga Khan Challenge Cup awarded to a 6-h.p. Wolseley Car in the recent Poona-Satara Reliability Trials.

Gaillon Hill Climb Records.—This is one of the oldest established of the late-season "Foreign Events," and for seven years in succession has been organised and stage-managed by our contemporary, *L'Auto*. It was last year's meeting, however, that aroused the first deep interest in the race on this side of the Channel, for it was on this occasion that Mr. Macdonald took the now famous, but then *débutante*, 6-cylinder Napier to compete against the foreign "crack" cars. Although in no way properly tuned to its work, Mr. Macdonald drove his car to such good effect that his time only differed by two-fifths of a second from that of the fastest.

The trial was exciting, and unquestionably astonishing to those who witnessed it, but the result was anything but conclusive—especially to an Englishman. Mr. Edge at once made up his mind, therefore, that his car should be given every possible opportunity for making a better performance in the following year, for he was certain, in his own mind, that it was capable of much better things. That "next opportunity" duly arrived on Sunday, the 15th inst., and the result of the race was that the time recorded was actually $3\frac{3}{5}$ secs. slower than the year before—a result as astonishing to us on this side of the Channel as was the previous performance to our rivals. We were, therefore, quite able to give credit to the report which reached us that the Napier was not in its best stride.

Nice Speed Races.—Arrangements have been concluded, it is reported, to resume the speed tests over the mile and kilometre on the Promenade des Anglais, at Nice, during the coming season of 1906.

Voiturette Competition.—The rules for this competition, under the auspices of *L'Auto*, now announced to take place from November 21st to 27th, starting from Paris, have now been issued.

The chief points are that vehicles to classify for entry must have one cylinder, with a maximum capacity of one litre; the weight of the chassis, including the bonnet, tanks, &c., must be between 350 and 500 kilogs. The body must be two-seated, at least, and weigh not less than 50 kilos., must have four wheels, and carry two passengers

of 70 kilos. each. Uncovered vehicles must carry 40 kilos. of ballast; hooded or covered vehicles must carry 20 kilos. ballast, permanently covered-in cars being exempt from extra ballast.

The trial will consist of four tests, viz.:

1. An endurance run of six stages, each of a distance of about 200 kiloms.
2. A speed test over a flying kilometre on the flat.
3. A speed kilometre on the hill with 10 metres flying start.
4. A run over 500 metres with a standing start and finishing at rest.

The endurance test of six stages is fixed for November 21-26, and the other three tests will take place on the 27th. The classing will be arrived at as follows:

- (a) *Regularity.*—Times will be officially taken at various points and stages of each day's running. The speed for each daily stage must not be less than 25 k.p.h. Any car making less average speed than this will, irrespective of the number of points that it may otherwise secure, be classed after all the competitors who have maintained an average of 25 kiloms. throughout the six stages. Competitors not maintaining the speed of 25 k.p.h. will be penalised for each stage by 5 points per hectometre per hour difference in speed.
- (b) *Speed Test on the Flat.*—A car making the best time over the flying kilometre will not be penalised. All other cars will be penalised by 2 points per second or part of a second between their time and that of the quickest car.
- (c) *Speed on the Hill.*—The same penalties hold good for the kilometre on the hill with a 10 metre start as over the kilometre on the flat.
- (d) *Starting and brake efficiency.*—500 metres test. The car making best time will not be penalised. All others will be penalised one point per $\frac{1}{4}$ second between their time and the time of the quickest.

The general classing will be arrived at by the addition of the 4 points, the lowest number denoting the winner, subject, however, to such winners having maintained the average speed of 25 kiloms. for the six stages of the endurance run.

Cars will be garaged free each night, and the garage will be strictly closed against all repairs, excepting under observance. Drivers may be changed daily under certain conditions.

German Heavy Vehicle Trials.—The heavy vehicle reliability trials of the German Automobile Club, which consisted of a number of runs in the neighbourhood of Berlin, commenced on the 9th instant at Reinickendorf, and finished up at Spandau on Saturday, the 14th instant. There were 13 classes, including everything, from 'buses designed to carry 23 passengers, and heavy luries for brewery work, to light delivery vans, entries being (a) by constructors, (b) by private owners. There were 16 entries altogether, and of the 16 entrants, 14 were at the start, the only defaulters being the steam lurry of Messrs. Garrett, Smith and Co., of Magdeburg-Buckau, and the petrol lurry of H. Rosenthal, of Berlin. Of the 14 competitors who started at Reinickendorf, 13 successfully accomplished the trial, and arrived safely at Spandau within the maximum time allowed, the

only failure to accomplish the course occurring in the case of the Cannstatt Daimler brewery lurry, which had been in use by the Böhmisches Brewery of Berlin for seven years, the springs of which gave out.

On each day of the Trials a "longer distance" of between 100 to 125 kiloms. was covered by the omnibuses, and a "shorter distance" varying from about 65 to 75 kiloms., by the luries. The awards are appended in the short table below.

The "Targa Florio."—The length of the circuit for this contest in Sicily, of which we gave a few leading particulars last week, will be 160 kiloms., which will be covered three times, making a total of 480 kiloms. In all probability the race will take place in May next.

THE Automobile Association's cyclist scouts will henceforth be patrolling the heavily-trapped part of the Portsmouth Road from Esher to the 19th milestone on every day in the week. This, we learn from the secretary, is the first step towards the *daily* protection against the unsportsmanlike conduct of the authorities, which it is the aim of the Association to "reform."

French Events in 1906.—The Committees sitting, in connection with the A.C. de France, to determine the main principles which shall govern the leading automobile events conducted by the A.C. de France next year, are gradually evolving innovations which are likely to prove of considerable interest both to manufacturers and the buying public. For the big touring events the suggestions are that classification shall mainly be by the power of the motor. That in each class the weight of the chassis and of the carriage portion and weight of passengers shall be specified separately, and also that uniform types of bodies shall be compulsory, the following being suggested: Cars with a speed of 30 kilometres per hour, "spider" body; 35 kilometres, double phaeton body; 40 kilometres, touring limousine type; the weight of each passenger to be 70 kilogs., with an allowance of 30 kilogs. for baggage. The replacement of tyres is to be a matter for very careful observation and record. A further proposition is that each vehicle shall carry an automatic recording instrument, which will permanently record the duration of stoppages of each vehicle, speeds, &c.

Automatic Starters.—M. Henry Deutsch de la Meurthe has offered a sum of 10,000 francs to be awarded by the Académie des Sports for the best automatic starting devices for the motors of automobiles. This money will be divided—the first competition, at which 5,000 francs will be awarded in prizes, is proposed

NOTE.—G.M. = Gold Medal. D = Diploma.

for December, 1905, and the next during the same month of 1906, both to take place while the Paris Automobile Salon is open. The rules of the competition have, by request, been drawn up by the A.C. de France.

The devices must be submitted in working order on a car having a 1, 2 or 4 cylinder engine, but if of the 4-cylinder type, the engine must be of at least 20-h.p. It must be capable of being operated from the driver's seat, and must work equally well with the engine cold or warm. The jury in making their awards will take into consideration, among other points, those of weight, size, simplicity, price, cost of upkeep, ease of action and facility for fitting to existing cars. Drawings must also be submitted, but will not be judged.

THE preliminaries for a lengthy tour of France in 1906 for motor bicycles, tricar, and voiturettes, are being arranged by *Les Sports*.

Vanderbilt Cup.—Owing to the fact that the A.C. de France, prior to the running of the Vanderbilt Cup, had formally notified the organisers of the Vanderbilt Race that whatever the issue of the race might be they would not take part in it for 1906 under the rules now pertaining, the French Club will not accept the custody of the Vanderbilt Cup with the condition that it should be

raced for in France next season. Baron de Türckheim, however, it is understood, has intimated that the French Club are prepared to offer suggestions to the Cup organisers regarding the rules in the future governing the race, under which the contest could be run in France.

Hallé Spring Wheel Trial.—The official report of the 4,000 mile trial which Messrs. C. S. Rolls and Co. have been conducting, under the auspices of the club, with a car fitted with a set of Hallé spring wheels—for which they are the agents—has now been published. The trial commenced on August 15th and extended to September 18th, a total distance of 4,001½ miles having been accomplished. Lubrication seems to have been the principal matter requiring attention, and, according to the report, oil was injected into the wheels on an average twice daily. After running 1,501 miles, the off back wheel was removed and sent to the works to have new spokes fitted. After running another 1,362½ miles, the same wheel gave trouble, and was sent to works to have a new rim, tyre, and spokes fitted to it. The near side back wheels also required new rim, tyres, and spokes after running 3,179 miles, but the front wheels came through the trial with only repairs to some split spokes *en route*.

MOTOR CYCLING.

PASSENGER CYCLE TRIAL.—Appreciation of a humorous incident. Mr. R. Todd is in the centre of our picture, just behind him is Mr. H. G. Reynolds (Judge and Starter) and Mr. MacKenzie is the Observer on the 6-h.p. Singer Car.

Quarterly Motor Cycle Trials.—The proposal to hold Quarterly 100 Miles Non-Stop runs for motor cycles, under the auspices of the Auto Cycle Club, to which we drew attention last week, appears well on the way to a successful issue. It is proposed that the trials shall be open to private owners, manufacturers or agents, and arrangements are to be made that all machines would be under strict observation the whole time. Certificates, in similar manner to that pertaining to the 100 miles car runs, would be issued stating number and causes of stoppages, the amount of fuel consumption, &c. Mr. F. Straight, the secretary of the Auto Cycle Club, reports that, so far, the majority of answers which he has

received in reply to his letter propounding the scheme, have been in favour of instituting these trials.

Passenger Motor Cycle Trial.—Sixteen motor cycles, each carrying a passenger in front, started last Saturday on the 125 miles reliability run organised by the Auto Cycle Club. Both start and finish took place from the Chequers Hotel, Uxbridge, and the route lay through Wheatley, Banbury, Bicester, Aylesbury, and Chesham. Times were taken up Dashwood Hill—from the 33rd milestone to the Danger Board—and a "surprise" brake test was

PASSENGER CYCLE TRIAL.—The start at Uxbridge.

made on the return journey. With the exception of an hour for lunch, no stops were allowed, and the competitors had to run in accordance with a schedule giving maximum and minimum times—estimated on the basis of 15 and 20 m.p.h. respectively. The following are the results:—

Official No.	Entrant and Machine.	Stops.	Petrol.	Hill-Climb.
			gls. pts.	m. s.
1	A. Carpmael, 6-h.p. Riley ...	3	3 0	5 14½
2	Quadrant Cycle Co., 6-h.p. Quadrant	N.S.	3 0	2 53½

NOTE.—No. 10 stopped the engine once momentarily. No. 16 did not finish. Nos. 5 and 11 had several stops. N.S. = non-top.

THOMAS, on a ½-litre Alcyon machine, on Sunday last, at the Paris Parc de Princes track, attempted to lower Cissac's world's record time on a Peugeot machine of 1h. 6m. 46½s. for 100 kiloms. for this class of machine. This he failed to do, but lowered his own previous time, under which he holds the Hydra Cup, from 1h. 10m. 1½s. to 1h. 9m. 2½s. for the 100 kiloms.

Had the Positions been Reversed.—A case in which the amazing idiosyncracies of the horse threatened serious danger to one of the most popular of our princesses occurred not so very long ago in the Bayswater Road, where Princess Henry of Battenberg was driving in an electric landaulette to the Queen's Hall. Without rhyme or reason, a four-wheeled cab without a driver dashed out from Palace Yard and came into collision with the Princess's landaulette which it considerably damaged, though fortunately the Princess escaped injury. The case came into the Westminster County Court and resulted in an amazing decision, it being stated that the cabman was not bound to hold the reins of his cab while putting up luggage, a view with which, we must say to our astonishment, the Judge agreed. In future, therefore, anybody who sees a cabman putting up luggage, or, in general, a horse without a driver, had better give it a wide berth, as, if the horse dashes off and into him, as horses frequently do, and a bad smash results, there is at least one County Court Judge who will think it is all quite right and proper.

PASSENGER CYCLE TRIAL.

REVIEWS OF BOOKS.

"The Little Guides." Dorset.

By FRANK R. HEATH.

(London: Methuen and Co. Price 2s. 6d. net.)

THIS is one of the best of the Little Guides Series that we have seen, and it is none the worse for the fact that photography has replaced the etching employed in its predecessors as a means of illustration. Dorset is a particularly interesting county, both from the archæological and geological points of view, and both these aspects of the district are treated with more than usual fulness and competence. Dorset is, of course, pre-eminently the Hardy country, and it is a testimonial to Mr. Hardy's genius that no guide book now attempts to describe his part of the country without paying particular attention to the places which figure in his novels. This is very carefully and skilfully done in the present work, and it forms in consequence quite a guide to Hardy geography—a feature which is facilitated by the appendix giving the names of places and their equivalent "Wessex" names in Mr. Hardy's books.

"The Locomotion Problem."

(By Charles Bright, F.R.S.E. London: P. S. King and Son. Price 1s. net.)

SOME two or three years ago Mr. Charles Bright delivered some lectures on this subject, partly at the Uxbridge Literary Institute and partly at Toynbee Hall. He has now re-issued them in volume form at the moderate price of 1s., and though, in some respects, of course, the subject matter is a little out of date, there is an admixture of humour and solid sense in the treatment he accords to the subject with which he deals, that renders the little work decidedly attractive reading. The three lectures comprised deal with (1) The Advent of Motors, (2) Roads, and (3) Traffic. Under the first of these headings—The Advent of Motors—the author provides a sort of running commentary on the existing acts, and in some places he makes very trenchant observations, as, for instance, where he observes, "Nobody resents the behaviour of a motor 'road-hog' more than rational motorists, who strongly object to seeing discredit brought on his fraternity by the ill-behaviour of certain individuals. The difference between barely keeping within the law, and behaving as a gentleman, does not appear to be sufficiently appreciated in some quarters, and motor car owners would do well to impress upon their drivers that it shows great lack of consideration for the comfort—if not the safety—of their comrades on the road to leave but a hair's breadth space when driving past them." And in all this part of the book, it must be admitted he most impartially points out both the disadvantages of the existing Act, and the strong objection, from every point of view, to infringing certain of its provisions. On the subject of road improvement and road management of the future, Mr. Bright is practically at one with the Roads Improvement Association and ourselves. The future of traffic is in his mind bound up with the discovery of some suitable substance (necessarily not too dear for making roads of), and in the arrangement of some central authority, as suggested by Mr. H. G. Wells and Mr. Rees Jeffreys, for controlling them.

To the enforcement of the regulations at regards town traffic, and to the general improvement in speed and comparative absence of blocking which will result from the adoption of self-propelled vehicles, Mr. Bright looks for considerable amelioration of the traffic of the future, though he is doubtful as to whether these things alone will cope with the rapid growth of population. We must certainly differ from him on the point that, in the future, all railways are destined to be electrically propelled. We think it is at any rate at least as likely, and probably more so, that the internal combustion engine will find an increasing field on them. Perhaps, after all, much of the traffic problem may be summed up in the humorous sentence with which the work opens: "There is an American phrase, 'Hustle,' which is placarded about the towns in the United States to get people along—whereas we spell it 'drive slowly.'" Rapid motion well regulated is, after all, the desideratum, and it is really less dangerous than slow locomotion unintelligently managed.

Cheshire.

By W. M. GALLICHAH. Illustrated by E. HARTLEY.

(The Little Guides Series. Methuen and Co. 2s. 6d.)

EXCEPTING for the illustrations to which the grand old Cheshire houses lend themselves with such excellent effect, this volume produces a less satisfactory impression than most of the other "Little Guides." This is perhaps partly due to the arrangement of places in alphabetical order being specially unsuited to Cheshire, a county in which places most particularly cannot be lifted out of their environment and described without reference to their surroundings. It is also more due to the practical failure of such attempt as is made to give a general impression of the varied scenic beauties of the county, in which respect the present volume is in almost painful contrast to some others of the series—notably those dealing with Yorkshire. Why, too, geology should be wholly omitted in the case of a district the structure of which is so scenically and industrially interesting, is something of a mystery.

PUBLICATIONS RECEIVED.

Motor Vehicles for Business Purposes. By A. J. Wallis-Taylor. London: Crosby, Lockwood and Son. Price, 9s. net.

Owner or Bailee?—A rather strange case came before Mr. Garrett at the South-Western Police Court recently, in which Mr. E. A. Robinson was summoned for not having properly registered a motor car. The car in question was lent to him by Mr. Marsh, who had registered the vehicle when residing in Jermyn Street. Mr. Marsh is at present in the United States, and the police apparently tried to make out that Mr. Robinson ought to have had the car re-registered in his name. Strangely, even Mr. Garrett seemed to have some doubt on the question, as he said; "The question is, what is the meaning of the word owner?" There can, we think, be no doubt on this point. Mr. Appleton, who represented Mr. Robinson, declared that his client was simply the bailee of the car for Mr. Marsh, and not only was there no obligation upon him to re-register the car in his own name, but it would have been an incipiently fraudulent act had he done so. Mr. Garrett concurred in this view, and dismissed the case.

CORRESPONDENCE.

* * The name and address of the writer (not necessarily for publication) MUST in all cases accompany letters intended for insertion, or containing queries.

PETROL, STEAM, AND THE CLUB.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I wrote to you about a fortnight ago asking certain questions. You very kindly published my letter, but I have had no answers of any kind to my questions. Are your correspondents inclined to answer the questions if put in a different way? I mean I have a friend who manufactures cars not driven by petrol. He tells me (I do not for one moment say that he is right):—(1) That the Tourist Trophy Race was a delusion and a fraud, got up by petrol car manufacturers entirely for their own advertisement; (2) that the A.C.G.B.I., instead of being representative of the motorists as a body, is merely a ring of petrol car manufacturers; (3) that the A.C.G.B.I. is greatly to blame for the persecutions and hatred of motorists in various parts of this country, as if it had from the first adopted a wider basis and been more united, it would now stand in such a powerful position that the motorist would everywhere be respected. He instances the Touring Club de France; (4) that all competitions got up by this body are unfair, and preferential to petrol cars alone. He instances several cases of the unfair treatment of steam cars, e.g. Blackpool; (5) that that is the real reason why unions and associations of motorists spring up hostile to or unconnected with the A.C.G.B.I.

Now, I would like to know, Is there any truth in these accusations? I should like to get an answer of some kind. You will doubtless recall the old proverb that "Silence gives consent."

Yours faithfully,

E. W. SHEPPEE.

Holly Spring, Blacknell,

Oct. 15th.

[Mr. Sheppee's previous letter appeared under the heading of "Tourist Trophy Race," in our Correspondence column of September 30th, and was signed "Inquiring Ignorance."—ED.]

THE DANGER OF FILLING WITH PETROL WITH THE DASH LAMPS ON.—A SENSIBLE WARNING.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I happened to be staying at the Swan Hotel, Alresford, a few days ago, when, sitting at dinner one evening in the coffee room of that fine old hotel, I heard a car draw up at the door, the owner and driver of the car rushing up the yard shouting "Petrol!" "Petrol!" "Petrol!" Hearing all this unusual amount of fuss, I left my dinner and went to see what car it was, expecting, of course, to see a 100-h.p. car at least, instead of which, to my surprise and disgust, I found about a 4½-h.p. tonneau car of some unrecognised make.

The owner, rushing about, first ordering soup, &c., to be taken out to the lady in the car as they *hadn't time* to stay for dinner, and they were in a *great hurry*. He then left for the post office to send a wire off (I expect to say that they had arrived safely from Winchester—9 miles), also leaving instructions to the chauffeur to fill up with water and petrol, and to feel the bearings, all of which I watched with a keen interest, until he came to the petrol, which made my blood boil, filling up the petrol tank, which was on the dashboard, with the dash lamps alight, a distance of about six inches from the filling hole!

I remarked to him, "Don't you think that is an extremely dangerous practice?" He replied, "Oh, no, I always fill up like this."

The lady in the tonneau hearing this thought, perhaps, I was right, so ordered him to remove the lamps, which he did. I told him that I was pleased that he had removed them, because had he not done so I should, as I had seen too many cars burnt up in the same way. I told him it was not his 1-h.p. car that I was considering alone, but the possible life of others and the Swan Hotel where I was staying.

He looked me up and down several times, wondering to himself who I was, but after carefully thinking the matter over went on filling up the petrol tank, perhaps exercising more care than he had ever done in his life before.

Chiswick, W.

J. RUSSELL SHARP.

THE ASTER ARGYLL AGREEMENT.

To the Editor of THE AUTOMOTOR JOURNAL.

Sir,—We notice in certain motor journals an extraordinary paragraph to the effect that the Société Aster of France has concluded an agreement with the Argyll Company whereby, among other

things, the Société Aster places an order for a number of motors to be manufactured by the Argyll Company at Glasgow.

It is perfectly correct that an important agreement has been made between the two Companies, and that the Argyll Company has been granted a licence to manufacture engines for their own cars only, as the Société Aster are unable to supply the enormous number that the Argyll Company demands, but the Société Aster has not placed, nor has any intention of placing, an order for engines with the Argyll Company or with any other firm.

ASTER LIMITED.

SYD. D. BEGHIE, M.I.M.E., Chairman.

Oxford Street, W.

A Fine Sample of "Justices' Justice."—A horse driver who was convicted at Grantham of furiously driving a horse through the town at such a pace that one of the police witnesses said he could not have pulled up in less than 100 yards, and generally endangering in consequence all the people in the street at the time, was fined the ridiculous and trifling amount of 10s. and costs.

Tolls on Bridges.—The Motor Union, which has already been instrumental in reducing the tolls for motor cars over several bridges owned by private companies and others, has scored another success in this direction. As a result of the complaints of the heavy charge of 2s. per car, charged by the Manchester Ship Canal Company for cars crossing the Warburton Bridge on the main road between Warrington and Salford with Altrincham, the Union wrote to the Company asking that the charge should be reconsidered with a view to a reduction. As a consequence the Company have advised the Motor Union that "in future the charge for ordinary touring cars weighing less than two tons shall be reduced to 1s. per car, subject, however, to the proviso that the speed over the bridge shall not exceed five miles per hour."

Plucky Motor 'Bus Officials.—Travellers by "Vanguard" motor 'bus on the Brighton road one day last week had a thrilling experience of the dangers of horse-drawn traffic. A heavy grocer's van with two horses was, as usual, left outside a house in the neighbourhood of Crawley. The horses happened to be frightened by some passing incident, and with that excellent common-sense which characterises the breed, at once made off along the road, van and all, just as the motor omnibus with all its passengers was approaching. Under the enthusiasm of a runaway, horses never count the odds, and these would probably have charged full tilt at the motor 'bus without considering that they would be smashed up in doing so, had not the driver and conductor (T. H. Jones and G. B. Hillier) of the latter jumped off, and with great peril to themselves, succeeded in stopping the horses' headlong career. It was a thoroughly brave act, and undoubtedly averted serious catastrophe. Several of the passengers on the 'bus have written to the company in praise of the bravery of the driver and conductor, and we are glad to learn that the company have suitably rewarded their servants. The occurrence, however, is a very forcible commentary on the extreme danger of the almost universal custom of tradesmen of leaving their horsed vehicles unattended outside houses. They, of course, can be fined for doing so, though with their usual partiality the police never summon them. All automobilists who come across cases of the kind would be performing a public duty if they proceeded to prosecute, or induced one of the great automobile bodies to do so.

AN ORIGINAL AND NOVEL "EXHIBITION."—The Winton Motor Carriage Company, of America, have devised an extremely novel form of exhibiting their new touring car models through the chief cities of America. They have specially adapted one of the big railroad cars for a travelling exhibition stand, on which their latest model is taken round the country and is open for general inspection at each of the principal cities in the United States. We give more detailed particulars of this novel installation on this page, and above we reproduce the exhibition car seen from the outside, and also an interior view of one end of the railroad car.

Winton Enterprise.—A novelty in the way of, we will not say advertising, but introducing a car to the notice of the public, has been organised in America by the Winton Company. The company is naturally desirous of bringing to the notice of American citizens (we believe that is the right term) the new Winton model for 1906. To this end they have chartered a special railroad car of the 60-foot express type which contains as sole freight the Winton exhibit. The railway car is embellished outside with scenes depicting the Winton factory, the Winton car, and other matters of interest, and is making a tour of the principal cities of the United States, including Detroit, Buffalo, Rochester, Boston, Cincinnati, Indianapolis, St. Louis, Chicago, Omaha, Milwaukee, St. Paul, Minneapolis, Kansas City, Denver, Sacramento, Salt Lake City, San Jose, San Francisco and Los Angeles. The railway car is provided with "skids" at either end which will enable the public to walk up and inspect the car from every point of view, an inspection which will be specially facilitated. The interior of the railway car is provided with a wide rubber platform, which extends the whole length, and broad rubber-covered steps also lead up from the ground. These are brought into requisition when the "exhibit is on full view." The ornamentation of the

interior is on an elaborate scale, large wide windows providing a superabundance of light, and at night electric light is provided by means of 200 electric incandescents. The exhibit, which is being thus magnificently stage-managed, consists of a chassis of specially high finish, a complete car with body in place, a second complete car used for demonstrations, and also a number of subsidiary parts such as cylinders, pumps, valves, crank-shafts and gears. In addition, ample office accommodation with desks, &c., is provided in the car. The tour is being commenced at a time when the weather in the States is likely to favour trial runs, and prospective purchasers in the main towns of the U.S.A. not only have an opportunity of seeing the best car the Winton Company can produce intact, but also of taking trial runs on a similar model. A feature of the arrangements is that Mr. Shanks, who is in command of the expedition, hands over his functions at every town it arrives at to the local Winton agent, and goes on with his ordinary business. On the whole, the expedition must be regarded as a very fine testimonial to American enterprise and advertising instinct. We reproduce a picture of the car complete, and an end view of the interior.

Royal Commission on the Motor Car Acts.—The sittings of the Royal Commission were continued during last week and this, Mr. Rees Jeffreys, the Secretary of the Joint Committee of the A.C.G.B.I. and Motor Union, concluding his very lengthy and important evidence on Wednesday of last week. On the same day, Lieut.-Col. H. Daniel, Chief Constable of Hertfordshire, also was heard, and on Thursday, Mr. Sidney Straker (President of the Society of Motor Manufacturers and Traders), Mr. S. F. Edge (on behalf of the Society), and Mr. T. F. Woodfine (the Secretary of the Society), and Mr. Mason Kidner (of the Jobmasters' Protection Association), gave evidence. This week the following have been amongst the witnesses:—Lord Dunedin, Lord Justice General and late Secretary for Scotland; Mr. E. White, Secretary to the Irish Automobile Club; Dr. E. B. Turner and Mr. Noble on behalf of the National

Cyclists' Union; and Mr. C. E. Beatty and Mr. E. R. Shipton, on behalf of the Cyclists' Touring Club. Amongst those who have been called for next week to give evidence is the Earl of Shrewsbury and Talbot, President of the Automobile Mutual Protection Association.

—
"Hedgehogs!"—a Comparison.—The Hon. Stephen Coleridge has been recently fined for driving too fast in Richmond Park, apropos of which experience he writes:—

I have no desire to throw any doubt upon the statement of the park keepers, that I was driving my motor car over ten miles an hour. It is a new car, and I was not very familiar with its paces.

But I wish to testify to the courtesy and tact with which the old soldier who stopped me did his unpleasant duty, and which contrasts so favourably with the truculent and irritating manners of the hedgehogs on the Andover road.

A contrast in roads used by hippomobiles (left) and by automobiles (right).

Road Destruction — Fact *versus* Fiction.—The Duryea Motor Company, of Coventry, send us the above interesting photograph of a contrast in roadways. The following letter from the Company is self-explanatory of the importance of the picture :—

"In view of the fact that one of the most important points which will be enquired into by the Royal Commission, which is now sitting to enquire into the working of the Motor Car Acts, will be allegations of certain rural authorities that motor cars cause undue wear on the roads, the accompanying photograph may not be uninteresting, seeing that it affords striking and visible evidence to the direct contrary. It represents the private road into the Duryea Works, and its significance lies in the fact that in the one photograph are shown

The 1906 Crossley Cars.—In addition to the new 40-h.p. model, of which we gave some particulars on September 16th last, the Crossley cars for next year will include a new 22-28-h.p. vehicle having many improvements over this year's pattern. Unfortunately, Messrs. Jarrott and Letts have decided not to exhibit them at Olympia, but we learn that they have already received a considerable number of orders for them. The 1906 improvements on the 22-28-h.p. model include the following:—The cylinders of the engine are of 4 mm. larger bore, being now 110 mm., with a stroke of 130 mm., and many of the moving parts have been reduced in weight, in order to enable the engine to run faster; greater facilities, moreover, exist for accurately adjusting the valve-gear and the rods that operate the igniters, as well as for examining the cam-levers that form a part of the latter mechanism. Each igniter now has double springs, instead of a single spring, and these are lengthened in order to prolong their life; the internal contact-arms also have a wider surface than formerly. Ball bearings of the D.W.M. type are fitted throughout the entire transmission, including the clutch and the gear-box, as well as the road-wheels, while other alterations that have been made to the chassis comprise an improved steering-gear working on ball bearings, a new form of expanding hub-brake, metal-to-metal foot-brake, longer side-springs, and a 10-ft. wheel base.

two roadways, one used exclusively by horse traffic, the other exclusively by motors. The road to the right is the original approach to our works, and when, a year or so ago, we undertook some work requiring the use of horse-drawn vehicles, as we found our road showed signs of getting cut up, we made the road seen on the left, and confined the horse-traffic to it. Both roads are very lightly made, just a paving of broken bricks with ashes on the top, and the average weight of our vehicles is about the same as the loaded weight of the horse-drawn wagons. The horse-road on the left, which is in very much better condition now than at times in the past, has been repaired three times, the motor road not at all since it was laid down two years ago. Comment, we think, is needless. The photograph tells its own story."

A New 12-15-h.p. De Dietrich Car.—Amongst the 1906 De Dietrich models, which are to be on view at Olympia next month, is a very interesting light car that has been designed for those who require one of moderate price built by a leading firm of makers. The chassis, which has a wheel base of 8 ft. 4 ins. and a track of 4 ft. 7 ins., can be fitted with a side-entrance, a landaulet, or a coupé body, and has a wide steering lock to render it particularly suitable for town use. It has side-chains, the gear provides four forward speeds, and the clutch is of the cone pattern. With its 870 by 90 mm. tyres, it is usually geared to about 30 or 35 miles per hour on the top speed. The engine, which has all its valves on one side, and its four cylinders cast in pairs, is controlled by levers placed above the steering-wheel, and by an accelerator pedal, while an unusual feature (for a De Dietrich car) is that the ignition system is of the high-tension magneto type—with sparking-plugs instead of low-tension igniters; the Simms-Bosch system has been adopted. The cylinders have a bore and stroke of 90 mm. and 120 mm. respectively, and a pressure-feed arrangement is used for the lubrication as well as for forcing the petrol from the tank at the back of the chassis up to the carburettor. As with all De Dietrich cars, good design and first-class workmanship are relied upon to render this model popular with the buying public. It is an extremely useful size of vehicle, for which there is undoubtedly a great demand.

A TESTIMONIAL TO AMERICAN ROADS.

A RACE was recently arranged across the great American Continent, a distance of 4,000 miles, between two Oldsmobiles (1,000 dollars being the stake run for), and the winning car, "Old Scout," duly arrived at Portland, Ore., having covered the 4,000 miles in 44 days 3 hrs. 28 mins.

The other competitor was stranded somewhere in the middle of Oregon, but will probably have arrived at the end of the journey by now. Whatever else may be said, it is a terrible testimonial to American roads that it is looked upon as a great performance by the Oldsmobile Co. to accomplish this distance in well over 44 days.

As, however, we learn that even the winning machine was several times turned over by the rough places (not made plain) which it encountered, was much discomposed by the swift mountain streams it had to ford, and the miles and miles of sand through which it had to plough its way, the feat is in reality a highly creditable one.

Under the circumstances a touch of humour is provided by the fact that the contest was, we are told, concluded under the supervision of Mr. J. W. Abbott, "Chief of the Rocky Mountains and Pacific Coast Division of the United States Government Bureau of Good Roads."

This "Bureau of Good Roads" in the United States is a conception worthy of Mr. W. S. Gilbert himself, and calls to mind the German work on the "Philosophy of the Non-existent," but we learn with satisfaction that the official of this bureau is confident that *when* good roads *are* introduced, automobiles will be able to cross the country on pleasure trips and for business. What some of the Oldsmobile "experiences"

amounted to may be gathered from the photographs which we reproduce, which certainly show that these

TOURING ON TWO OLDSMOBILE CARS IN AMERICA.—1, Trying to decide which is the best "jumping-off" point. 2, "Old Steady's" front wheel after wading through Illinois mud. 3, "Old Scout" taking its morning bath in Nebraska.

pertinacious little cars are not to be "stopped by trifles."

The 1906 De Dion Cars.—Another important stage in the gradual, steady, and sound development of the De Dion business is rendered evident by their programme for next year, for they have not only added a larger 4-cylinder model to their already comprehensive list of famous vehicles, but intend, later on in 1906, to place on the market a cheaper 6-h.p. car than the present single-cylinder vehicle of that power. Apart from the new 6-h.p. model—of which it is improbable that any delivery can be made before June—there will be the already well-known 6-h.p. vehicle, and cars of 8-h.p., 9-h.p., 12-h.p., 15-h.p., and 24-h.p. Of the last-mentioned series, the 8-h.p. and the 9-h.p., both have single-cylinder engines (of 100 by 120 mm., and 110 by 130 mm., bore and stroke), but the former has a tubular frame and a change-speed-gear of the individual clutch pattern, whereas the latter has a pressed-steel frame, a sliding spur-wheel gear, and the maker's special disc clutch; the 9-h.p. chassis is, moreover, made in two sizes, for long or for short bodies. The 12-h.p. car follows the lines of the

9-h.p. chassis in respect of all the points which we have just enumerated, except that the engine has a pair of cylinders, the bore and stroke of which is 100 by 110 mm. This twin-cylinder engine, like those having four cylinders, is fitted with magneto ignition, having dry batteries as a stand-by. No less than 300 lbs. has been taken off the weight of the latest 15-h.p. chassis, and it now has the engine-controlling levers above the steering wheel. It, too, is built in either of two lengths to suit various kinds of body, and naturally has a pressed-steel frame, a metal disc clutch and sliding-spur-wheel gear, as this year. The bore and stroke of the cylinders are 90 and 110 mm. respectively. Except that the 24-h.p. engine is more powerful, and the chassis altogether stronger—with four forward speeds instead of three—the design of this largest De Dion car resembles that of the 15-h.p. model. The chassis is, however, made in one size only, and that is of ample length to accommodate any required form of body. This largest De Dion engine has cylinders of 104 mm. bore by 130 mm. stroke.

CLUBS AND ASSOCIATIONS.

Proposed Essex County Automobile Club.—The following representative and influential automobilists have agreed to serve as a provisional committee for the purpose of forming the Essex County Automobile Club, to which we referred recently:—The Earl of Warwick (Dunmow), J. Gurney Fowler, J.P. (Woodford), G. C. Tijou, F. C. Hill (Wanstead), H. L. Osborne (Brentwood), J. Mason (Manor Park), R. L. Curtis (Prittlewell), E. E. Bentall, J.P. (Heybridge), F. G. Clements (Romford), Col. R. P. Davis (Walton-on-the-Naze), E. Bryant (Romford), Col. Tufnell, J.P., D.L. (Chelmsford), A. H. French (Galleywood), Dr. Montagu Tench (Great Dunmow), Dr. A. Butler Harris, M.A. (Loughton), B. Tabrum, J.P. (Brentwood), A. G. Reynolds (Woodford Green), Col. Lockwood, M.P. (Romford), T. Clarkson (Chelmsford), H. M. Fletcher (Loughton), Claud Crompton (Chelmsford), A. L. Buisseret (Ilford),

The medal of the Motor Yacht Club which has just been completed after the design by Mr. E. Fuchs.

MOTOR BOATING.

Coupe de "L'Auto."—For the third year this annual fixture for motor boats took place on Sunday last at Maisons-Laffitte, on the Seine, above Paris, as usual under the joint auspices of the Helice Club and *L'Auto*. Splendid weather favoured the meeting, and a good crowd gathered to witness the start, but there was only a very meagre show of starters; in fact, taking it all round, the 1905 motor boating season on the Continent has proved a fiasco from beginning to end.

In the Racers only three participated. Of these Rapee III. experienced lubrication troubles, and had to leave the race, over the 100 kilometre, for Antoinette III. to finish in 2h. 34m. 17s. The third racer was Bayard-Clement, which covered the course in 3h. 17m. 30s.

In the Cruiser class, Forcés Pas had the misfortune to miss the turning buoy and covered 6 kiloms. in excess of the 50 kiloms. constituting the race. In spite of this she managed to make the time of 1h. 38m. 2½s. against the time of Delahaye IV., the first, in 1h. 30m. 30s. Subsequently this race was annulled and permission given to Forcés Pas to re-run it on Sunday next, October 29. In the small class Mendelssohn recorded the best time over 25 kiloms. of 1h. 3m. 16½s., this boat ultimately winning the Maisons-Laffitte Cup (over 50 kiloms.) in 2h. 8m. 11½s.

THE opening of Kingsway, the new thoroughfare through the Metropolis, to the public, has been very appropriately signalled by the inauguration of a further motor omnibus service along it. The London and Suburban Omnibus Company have arranged a 10-minute service between the Law Courts and Chalk Farm, passing along Aldwych, Kingsway, and Southampton Row, through Seymour Street and Camden Town. From all that can be judged of the present success of the venture and the crowded condition of the vehicles, even a 1-minute service would be perfectly successful.

Dr. Leigh Day (Colchester), Kenneth S. Storrs (Chelmsford), R. W. Wakelin (Witham), F. Lindus Forge (Woodford).

A meeting of this committee will shortly be held at the Great Eastern Hotel, Liverpool Street Station. A representative meeting of the automobilists in the county will be held at the same place at a subsequent date, notice of which will be given.

The Society of Motor Manufacturers and Traders.—By way of rounding off the important statistics which the society have been able to get together from the motor trade for the purpose of laying before the Royal Commission on the Motor Car Acts, a number of very important concerns were amongst the final lists of firms to send in returns to the society, including such important manufacturers and firms as New Arrol Johnston Company, Limited; Swift Motor Company, Limited; Argyll Motors, Limited; Belsize Motor Car and Engineering Company, Limited; H. H. P. Deasy and Co., Limited; Carl Opperman Electric Carriage Company; White Steam Car Company; Bristol Motor Company.

Yorkshire A.C.—The opening of the club's winter season will take the form of a smoking concert on Wednesday, Nov. 8th.

FROM the statistics compiled by the Joint Committee of the A.C.G.B.I. and Motor Union, it transpires that the total approximate mileage travelled by owners of cars who have sent in returns amounts to 44,352,300. Only 16 fatal accidents have occurred.

PASSENGER CYCLE TRIAL.—At Waltham Cross, Mr. G. H. Fell on the 6-h.p. water-cooled Fafnir.

Motor Manufacturers and Traders at Olympia. The gathering was of quite an informal character, and was one of the most enjoyable at which, for some time, it has been our pleasure to assist, "mine host" Coleman subsequently providing an excellent entertainment in place of the speech-making which is usually considered such an essential feature of "thanksgiving" meetings of this nature.

H.H. the Maharajah Shri Chhatrasinhji, Rajpipla State, at the wheel of his 6-h.p. Wolseley light car.

A CASE was positively dismissed by the Morpeth Petty Sessional Magistrates recently, in which Charles Hills, chauffeur to Viscountess Ridley, was accused of driving to the danger of the public. The police, of course, said that he was going at $28\frac{1}{2}$ miles an hour exactly, but Lady Ridley said she was sure that he was not going at more than 15, and for once the Bench believed a lady rather than the police, and dismissed the case.

WITH the approach of winter, automobilists are again confronted by the problem of successfully presenting all possibility of the water in the circulating systems of their cars becoming frozen. Glycerine has long been recommended for the purpose, and Mr. S. F. Edge recently requested Mr. Veitch Wilson to carry out some tests so as to decide what proportion of glycerine renders water unfreezable. From Mr. Wilson's experiments, it appears that water containing 20 per cent. of glycerine will freeze at $27\frac{1}{2}^{\circ}$ Fahrenheit; with 30 per cent. to 21° , or a 40 per cent. solution freezes at zero. Mr. Edge accordingly recommends from 20 per cent. to 25 per cent. of glycerine, which costs, wholesale, about 7s. 6d. a gallon, being added to the cooling water in motor cars during the winter.

A THOROUGHLY delightful little meeting of friends and pressmen took place last week at the Criterion Restaurant, when Mr. Frederic Abernethy Coleman, so well known as the British representative of the White Steam Car Co., celebrated the introduction of the first 1906 models of the White car, which have recently arrived in London, and which will form one of the features of the November Exhibition of the Society of

THEY arrest people for nearly everything in America; in fact, any offence for which only a summons is issued in this country entails finding yourself in the clutches of the police in the great Republic of the West. For improperly distributing handbills about the town of Los Angeles in violation of the city ordinances, an aeronaut of the name of Burke, in the employment of Mr. Alva Reynolds, was being pursued by the minions of the law, who chased him upstairs to the top of a building, where, no doubt, they thought they would nab him nicely, like a rat in a corner, or a rabbit at the end of its burrow. But the police had not allowed for the fact that, tethered to the top of the house, was Mr. Reynolds' navigable balloon.

JUST before the police reached the top of the building, Burke reached the car of the airship, and, cutting loose, sailed away in triumph, favouring the police, who were just too late, with what some of the eye-witnesses of the scene have described as "a gesture of derision." He then circled to and fro over the town, distributing the handbills still further, the police watching him meanwhile in impotent indignation.

INDIAN MOTOR TRIALS.—Since the Delhi Bombay Trials held in January this year, the cars which were successful in that event have been much sought after, not only by European residents but by a number of Princes and rulers of native states. We are able this week to give some photographs—in addition to the above, in which Mr. Taylor is seen at the wheel of his 6-h.p. Wolseley Car at the completion of the Delhi-Bombay Trials—of two of the Indian Maharajahs who have pinned their faith to this well-built little British vehicle. These are seen on this page.

H.H. the Maharajah of Nandos on his 6-h.p. Wolseley light car.

ON Tuesday of this week the new Manx law, restricting the speed of motor cars to a maximum of 14 miles an hour, was promulgated from Tynwald Hill, and from that date has, therefore, come into force.

WHENEVER County Councils happen to be a bit progressive, it often occurs that they find their bitterest opponents among the "dignitaries" of the District Councils over whom they exercise jurisdiction. The Faversham County Council has been very wisely proposing a certain expenditure for tarring some of the main roads, a treatment which, it has now been proved, pays for itself by diminished upkeep in a relatively short space of time. The Blean Rural District Council, however, is very angry, and has enclosed a resolution to the Faversham Council, stating that they "view with dismay the proposed expenditure on tarring to prevent dust which is caused mainly by motor cars."

Only a very slight idea is conveyed by the above photograph of the extremely handsome carriage that it represents. The car is one of the new 18-h.p. White steam vehicles, which are to form one of the attractions at Olympia next month, and all of which are exceptionally well-finished specimens of British carriage-work. We gave, in our issue of September 30th last, a fully illustrated description of the 1906 type of chassis, which by its construction now enables steam cars of this type to be built.

EARL RUSSELL was one of the team of motorists arraigned before the Guildford Bench on Saturday last charged with having exceeded the speed limit through the police trap at Milford—most of the teeth of which, we believe, have been since then drawn by the Automobile Association—on September 30th. Earl Russell defended himself, and delivered an eloquent address on the whole situation, the demoralising character of police traps, the tendency of the tactics pursued to interfere with the efforts that were being made to eliminate the reckless driver, and the evil results in country districts, where the villages are denuded of police protection in order that these functionaries may lurk in hedges. The speech was absolutely conclusive, incontrovertible, and unanswerable, and the Guildford magistrates heard him stolidly through, and then fined him £10 and costs.

EARL RUSSELL has, in fact, had a run of bad luck. At Kingston Quarter Sessions, at the same time that he was fighting the Guildford case, his appeal from a previous conviction and a fine of £5 for exceeding the speed limit at Shottermill came on for hearing, and was dismissed, the conviction being affirmed with costs. Earl Russell was, on this occasion, represented by Mr. E. A. Jelf.

ONE of those acute officers of the law who can always see when there is something wrong with a motor car, though a tramp stealing cabbages in broad daylight generally escapes their notice, happened to be passed by the King's automobile at Carnforth recently. The Royal car, of course, bears no identification plates, and the policeman was all agog with visions of a possible summons to know what it meant. He telephoned to a sergeant at Skerton, and the sergeant came out to stop the car, when matters were explained to him by the driver.

MR. SOMERS SOMERSET has been drawing attention to the remarkable utterances of a Fareham magistrate. In a recent case, in which a motor bicyclist was arraigned for driving to the danger of the public, the police maintained that the defendant drove past a cross-road at sixteen miles an hour, but the defendant maintained his speed to be considerably less than this. The discussion was cut short by one of the magistrates, of the name of Radcliffe, who said that even five miles an hour would be dangerous, and that the defendant had therefore driven to the danger of the public, and without more ado put the fine at 40s. To be logical, this charming magistrate evidently should maintain, as very probably in private life he does, that to ride a motor bicycle at all is to endanger the public.

ON Monday Mr. W. T. Smallwood, of Lewisham, was fined 40s. and costs, at Bow Street Police Court, for turning his motor car round in Norfolk Street, Strand, without giving warning, by which act, it was alleged, he nearly knocked down a lady and gentleman who were crossing the road, the defendant, however, denying that anyone was in danger. Without discussing the merits of this particular case, the fact that the turning round of a vehicle in a London street suddenly, without warning, is punishable by a fine, should open up a grand source of revenue for the country, provided the fines can be directed into the National Exchequer. From personal experience we should judge that there should be sufficient fines raked in from cabmen and other drivers of horse-drawn vehicles in this respect to entirely do away with the obnoxious Income Tax, and ultimately wipe out the National Debt in a comparatively short period. But we fear that the attentions in this respect are likely to be confined to motor cars, whilst cabs and other horse-drawn vehicles are allowed to go on their old sweet way of suddenly having their horses jumped round on to unoffending passers-by without the slightest warning of any sort.

WE regret to record the death, on Friday of last week, of the wife of Mr. T. W. Staplee Firth, the well-known solicitor, who has, from the commencement of the automobile movement, been so intimately associated with legal cases referring to motoring.

THE total number of cars and motor bicycles registered by the London County Council since the Motor Car Act came into force now amounts to 8,059 and 4,808 respectively. The numbers registered between July 1st and September 30th of this year amounted to 954 motor cars and 371 motor cycles, 2,951 licences being applied for and granted during the same period. The total number of licences issued by the Council since the Act came into force now amounts to 22,549.

WE learn from Mr. Stenson Cooke that in certain sections of the Press—not, it is almost superfluous to say, of light and leading—the activity of the Automobile Association has been subjected to criticism, and a suggestion has been made that “there is such a thing as interfering with a policeman in the execution of his duty,” &c., &c. We do not think the Automobile Association need fear trouble on this point. To lie in wait and, in effect, to aid and abet in the commission of offences instead of preventing their commission is no part of a policeman's duty, as recognised by law. There have been summonses taken out on this point we know, and Petty Sessional magistrates, ignorant, as usual, of the law, have in some cases inflicted fines; but there is no doubt that if the case were appealed upon to the Divisional Court any such absurd decision would be upset.

A PRETTY bad example of what appears to be unpardonable negligence, resulting in a very serious accident, which, but for the gallantry of the spectators, might have had fatal results, occurred on Sunday last at Liverpool. The regular ferry boat for Birkenhead was about to leave the quay when a Clement car belonging to Mr. Paul Cinquevalli, the famous conjuror, was being put on board, and was partially on the gangway and partially on the steamer, when those in command of the steamer, it is reported, without taking any notice of the circumstances, started the vessel off, with the result that the motor car was precipitated into the water, turning a complete somersault on the way, the driver and a Miss Morris, who were in the car, being carried down below the surface of the water. A gentleman named Cadercio took off his coat and immediately jumped to the lady's rescue, and secured her as she came unconscious to the surface, when, by means of a life-line, both were drawn ashore, the driver being rescued by a ferryman.

A MOTOR bicyclist, Frederick Charles Payne, who, as will be remembered, on August 20th last, fired a revolver through the hand of one of a number of sailors and bargemen, who, he thought, were going to assault him on a road near Maidstone, was sentenced at the West Kent Quarter Sessions held at that town last week, to a fine of £10, and to be bound over in £20.

SINCE the Vanguard motor 'buses became a feature of the Metropolis, on March 30th last, the original service of three cars has been increased to 45, with five cars held in reserve, and altogether upwards of four million passengers have been carried by them. The Motor Omnibus Company intend next summer to make a regular feature of hiring out Vanguard omnibuses for private parties of not more than 16 people for tours in the provinces.

A FURTHER method of irritating and annoying automobilists has been adopted, we cannot say invented, by the magistrates of Steyning. A Tooting motorist, who was summoned for driving in excess of the speed limit, failed to appear before them, and they accordingly issued a warrant for his arrest. This is a very unusual proceeding, though we remember it once before being done under aggravating circumstances by the Worthing Bench; but it is strictly within the magistrates' powers to do so. Needless to say, however, if it were anything but the case of an automobilist, the defendant would be convicted and fined in his absence, and there would be no further bother about it. But the chance of compelling the attendance of a representative of the hated locomotion, in the clutches of policemen (handcuffs will be used next), is an enjoyable spectacle which the Steyning magistrates could not bring themselves to forego. They are especially virulent, as a matter of fact, owing to the result of a recent appeal from one of their decisions to Quarter Sessions, so all automobilists arraigned before the Steyning Bench had best beware.

The Hon. Charles Weld Forester was the second private owner who was able to obtain delivery of a 20-h.p. Brotherhood Car, and since March, when the earliest deliveries were made, he has made constant use of his carriage, for both short distance working and long distance tours, covering in the period a minimum of between 6,000 and 7,000 miles. A feature to which Mr. Forester, who is at the wheel of his car in our photograph, has drawn attention is his appreciation of the simplicity of the Brotherhood Car, whereby he has been enabled with practically little or no mechanical knowledge, to undertake long tours without being accompanied by or finding the necessity for a chauffeur.

moment, he considers better than when he originally had it delivered.

His many friends amongst motorists, and in the automobile industry, will be glad to hear that Mr. Henry Fowler has been appointed by the Midland Railway Company, assistant works manager of their locomotive department, in addition to retaining his post as gas engineer. Mr. Fowler has not only made a special study of self-propelled road vehicles, but has always been ready to give his cheerful assistance in connection with all important automobile events—from the time of the heavy vehicle trials in Liverpool onwards.

THE PRIME MINISTER'S NEW CAR.—Mr. Balfour has just taken possession of one of the new 60-h.p. six-cylinder live-axle Napiers. This is the fifth car which the Prime Minister has had, and it is interesting to note that although Mr. Balfour keeps scrupulously up-to-date as regards the chassis, yet he still makes use of the "tonneau" in preference to the "side-entrance" type of body.

A PROPOSITION is on foot to have a monster demonstration in Paris on Sunday, December 17th, in connection with the Paris Automobile Salon, of all the industrial vehicles available. The idea is for them to form an imposing procession and travel over a distance of about 60 kiloms. in and about Paris, finally returning to the Grande Palais.

THE inquest on W. W. Collins, who was killed whilst accompanying Mr. Arthur Brown on his racing car in July last, between Newhaven and Brighton, was resumed and closed on Monday at Newhaven. An affidavit was read from Mr. Arthur Brown, the owner of the car, that he was personally driving and at a moderate speed, and in view of the fact that the doctors reported that it was doubtful when, if ever, Mr. Brown would be able to attend the inquest, the jury returned a verdict of death by misadventure.

THE starting of large petrol motors naturally requires a very considerable amount of power, and therefore any simple method of performing it without complication would be a distinct acquisition. Hitherto, auxiliary engines or compressed-air reservoirs have been necessary, but now the Wolseley Company have hit on the happy expedient of using cordite cartridges for the purpose. The cartridges are easily inserted in the cylinder-heads, and the necessary firing gear is simple. At present, this system has been used very successfully by them on their new 140-h.p. six-cylinder engine, built for an American motor railway coach.

A REPAIR bill including only one inlet spring, one exhaust spring, and a new pump-nut, the latter being broken by a mechanic over-screwing it, is as modest a record as any car owner could wish for. This is, we learn from Mr. J. E. Bush, the outcome of using his Beeston-Humber car in covering a distance of about 2,000 miles over a period of six months. Mr. Bush states that the car has had "in and out" running in his district, which is a very hilly one, in all weathers, day and night, and if anything the car, at the present

At the Roheny Petty Sessions recently (in Ireland), the Chairman, Mr. T. L. Plunkett, D.L., called the attention of the police to the great danger caused to other road users by carters carousing in public-houses and leaving their horses and carts unattended outside. He was also in favour of County Councils compelling carters to carry lights on their vehicles, as they were the most dangerous class to be met with on the roads.

PEOPLE of the kind who join the Highways Protection League have sometimes waxed quite facetious in the remarks they make about motorists arraying themselves in the skins of wild beasts. They will now have another text on which to descant, the most recent invention reported being a motor coat made of the skin of that dread serpent the South American anaconda, which is practically as big as a boa-constrictor, and dreadfully poisonous at the same time. By special treatment it has been found that his skin can be so prepared as to cause the scales to permanently adhere to it, and this makes, it is alleged, a very light, pliable, warm, and watertight coat. As the colour of the anaconda is brown picked out with gold, and further adorned with black spots, motorists in goggles and anaconda skins are likely indeed to look something of a terror to those who do not sympathise with them.

MR. GUS ELEN, the well-known comedian of the "Halls," is making a motor car tour from his house near Clapham Common to Blackpool, in which he is attracting a considerable amount of attention by arranging to bestow a souvenir upon everybody along the route who happens to recognise him, and gives evidence of his recognition by waving a handkerchief. He was first recognised by a policeman near the Swan at Stockwell, who behaved "in the usual manner" as if he formed part of a police trap, but on receiving the souvenir from Mr. Elen, the constable dissembled whatever connection he might have had with any such underhand arrangement, and smilingly accepted the gift. In fact, Mr. Elen says that the police all along the route were the first to recognise him, and became so engrossed with the mementoes bestowed upon them that they failed to take any notice of the speed at which he was proceeding. Possibly this method of dealing with the police generally may be found useful by other automobilists, and we present the idea (free of charge) to the Automobile Association.

POLICE PROCEEDINGS.

Motoring Schools and Premiums.—Before Mr. Curtis Bennett, at Westminster, George Stephenson, 27, of Royal Avenue, Chelsea, and Harry McAllister, 27, of Richmond Road, Dalston, were charged, on remand, with conspiring to obtain money by false pretences and with obtaining various sums by fraud and misrepresentation.

Mr. Williamson, prosecuting on behalf of the Public Prosecutor, said the evidence would disclose a cruel and wicked system to obtain sums of money as premiums from young men desirous of being motor car drivers. Prisoners extensively advertised in very glowing terms that more motor drivers were wanted, that they had the finest establishment in London, that unlimited tuition was given, and that appointments were found for applicants who became pupils. By these advertisements young men were induced to apply at the Buckingham Gate Garage, Victoria Street, and sums of about five guineas were readily obtained from many who could ill afford to lose the money. Practically all the tuition given by the accused consisted of some chalk drawings on a blackboard, a description of an old cylinder, and one or two motor drives along the Embankment or in Battersea Park. The cars shown as belonging to the garage were, in fact, only stabled there.

James Alfred Hembrey, formerly a public-house manager, said he answered prisoners' advertisement on August 30th. A week or two afterwards, being dissatisfied with the teaching, and what he had heard, he asked about the return of his premium. McAllister wrote him a certificate that he was a good mechanic and careful driver. The testimonial was of a very laudatory character, and with it witness got a situation as a driver. But he was only there two days. He got on very well while driving about with another coachman, and acting as footman. The owner asked him to try his hand on a new motor, a 30 or 40-h.p. Daimler. He got up and pulled the wrong lever.

Mr. Williamson: What was the result? Witness: The result was that I got the sack on the spot.

Witness and others were severely cross-examined by Mr. Wildey Wright, for the defendant Stephenson, who, it was said, went to Yorkshire to raise money to carry on the garage when the sheriff was put in possession. It was also said, for the defendants, that they had given good practical lessons to the several prosecutors.

Mr. Curtis Bennett remanded the prisoners, bail in £100.

COMMERCIAL POINTS.

AMONGST others who purchased cars last week at one of "The Motor House" weekly auction sales, were the Baron de Blaquiere and the Earl Annesley (Viscount Glerawly).

THE Continental Tyre and Rubber Company (Great Britain), Limited, inform us that from the 25th of October their prices for Continental motor tyres have been advanced five per cent. on account of the continued rise in raw rubber. The advance came into force on the date mentioned, with the exception of those cases where their customers have made firm contracts. In such instances the increase will take effect on the expiration of such existing contracts.

MR. WALTER W. BANNISTER has just opened repair works and garage at 62, King Street, Maidstone, lately occupied by Messrs. Loder, coachbuilders of a century standing. Mr. Bannister has installed electric light, pit and washdown on the ground floor, whilst a lift for small cars to the first floor has been erected, where electrically driven tools, steam vulcanising plant, &c., are available. The garage is on the main London-Folkestone Road.

THE Mersey Railway Company's new omnibuses, to which we referred in our issue of the 14th inst., are, we learn, being fitted with Royal Sirdar buffer tyres. In addition, Royal Sirdar buffer tyres we learn are not only also fitted to the "Arrow" motor omnibuses, of one of which we gave an illustration last week, but to the Rennie and Prosser motor lorry, of which a picture was also given in the same issue, and on the same page.

THE Rover Cycle Company, Limited, this week decided to alter their name to the Rover Company, Limited.

MR. A. DARRACQ, one of the heads of the Darracq firm in France, has shown his very warm appreciation of the Dunlop tyres

in their association in the victory of Hemery's Darracq car in the Vanderbilt Cup by writing to the Dunlop Company as follows:—
"We are delighted to state that your tyres have come through this difficult trial in a manner which fully justifies the confidence we placed in them."

A NEW and extensive repair department has been just completed by the Daimler Motor Company at their works in Coventry. The completion of this has been materially expedited in view of the requirements of owners, who find it advisable to have their carriages overhauled in the autumn rather than in the spring, when the manufacturer is usually overwhelmed with work. The Daimler Company, by this new installation, are able to deal expeditiously with all repair work entrusted to their charge.

Expert Tyre Repairers.—We are informed by Messrs. Harvey Frost that they have trained a number of youths in the art of repairing tyres by their process, and that several of these are available for accepting new positions. No doubt there are many who would be glad of the opportunity to engage someone known to be competent in this work, for most motorists know from experience how much they can save by the judicious care of their tyres.

THE Eadie Manufacturing Company, Limited, the well-known makers of cycle and motor fittings, by their report show profits of £47,132 in 1905 against £30,685 in 1904.

THE directors of Aster, Limited, are paying a dividend of 15 per cent. on the ordinary shares of the company, after allowing for the 6 per cent. preference dividend on the first year of their trading, ending September 30th last, and are placing £6,000 to reserve for investment.

THE Swift Cycle Company, Limited, for the past year show by their accounts earnings amounting to £35,000. Out of this the directors propose to pay a dividend of 10 per cent. on the ordinary shares, and they report that the demand for the company's motor cars has much increased, until the present factories are insufficient to meet their requirements, and provision for further extension is therefore now sought.

THE season of the Sunbeam Motor Car Company, of Wolverhampton, has been a successful and satisfactory one, by the report of the directors recently issued. The profit of the year amounts to £3,808, out of which the directors are paying a dividend of 7½ per cent., the balance being appropriated to reserve, formation expenses, goodwill, carry forward, &c. Prospects for the coming season are good, and the directors report that orders are already booked for a considerable proportion of the output.

It is evident from the above photograph that, even if some motorists are apt to over-lubricate their motors, there are others who do not. The parts shown in our illustration were once a connecting-rod and a gudgeon-pin in a three-cylinder Brooke engine, but it will be noticed that—apart from more brutal injuries finally sustained—the latter is not only fractured but half worn through, and that the corresponding side of the bush in the latter is quite worn through. How an engine in such a condition could have been kept at work so long, and the inevitable "knocking" be put up with, is somewhat of a mystery, but no one will be surprised to hear that a crash came at last, and that absolutely no oil was present in the crank-chamber.

NEW COMPANIES REGISTERED.

East Berks Motor and Engineering Company (Limited), Wokingham Road, Bracknell, Berks. — Capital, £10,000 in £1 shares. Object, to acquire the business of motor car and cycle agents, &c., of E. Eatwell and M. J. Sale, at Bracknell, Berks.

• **Fred. W. Baker (Limited)**, 59, Hagley Road, Stourbridge. — Capital, £10,000 in £1 shares. Object, to acquire the businesses (1) carried on by the West Midland Motor and Cycle Company, Limited, at New Road; (2) the business carried on by F. W. Baker at Oldwindsford; and (3) the business carried on by the executors of the late A. Pearson at 59, Hagley Road, all in Stourbridge, Worcestershire, of manufacturers of and dealers in motor cars and motor and other cycles of all kinds, &c. First directors F. W. Baker, F. Cremononi, T. Robinson, and F. Gibbons.

Public Motors (Limited), 11, Queen Victoria Street, E.C. — Capital, £1,000 in £1 shares. Object, to carry on the business of motor car and omnibus proprietors.

Rosling (Limited). — Capital, £10,000 in £5 shares. Object, to take over the business of A. Rosling, motor engineer and manufacturer, carried on at Chelmsford. A. Rosling is permanent governing director.

The Scottish Motor Engineering Company (Limited). — Capital, £40,000 in £1 shares. Object, to take over certain

property at Granton, near Edinburgh, and to carry on the business of motor car manufacturers. (Scotch Company).

THE Scottish Motor Engineering Company, Limited, has, we learn, been established in Edinburgh, with works situated at Granton, on the Firth of Forth. This engineering scheme is particularly aimed at the construction of motor buses, vans, luries, and agricultural motor implements, and is another instance of the appreciation by Scotland of the huge possibilities of the motor vehicle in the near future. The works stand on seven acres of land, and those who have associated themselves with the company as directors are: Mr. William Alexander, of Stirling, who is chairman of the company, and is managing director of Ogston and Tennant, Limited, of Glasgow; Mr. Lewis Maclellan, of the firm of Lewis and John Maclellan, engineers, of Glasgow and London; Mr. G. Vincent, of the Auto Van and Bus Company; and Mr. J. Clingoe, who has been connected with several London firms. Mr. Clingoe will take up the position of managing director. We are informed that the construction of the mechanical portion of these vehicles will be particularly simple and of such a character that a minimum of special training will be required for the purpose of becoming efficient in driving them in ordinary commercial practice.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E., Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

2127. February 3rd, 1905. Improvements in Internal Combustion Engines. Henry Campbell, 13, Westbourne Crescent, Salterhebble, Halifax, Yorks. The improvements comprise means for altering the positions of the cams which actuate the inlet and exhaust valves of the engine, and for admitting compressed air or other gas from an outside source to start the engine. There are two figures. Fig. 1, is an end elevation, partly in section. *a*, is the crank-shaft, and *b*, a horizontal cam-shaft running along the side of the cylinders and carrying the cams for actuating the inlet and exhaust valves, which cam-shaft is an engine having one impulse for every two revolutions of the crank-shaft, requires to be rotated at half the speed of the engine. This rotation is effected by means of an intermediate

for the reversal of the direction of the engine's revolution. To raise the intermediate shaft, *c*, a grooved collar, *i*, is secured in a convenient position thereon, the grooved collar being engaged by one end of a bell-crank lever, *j*, actuated by a screw, *k*, from handwheel, *l*. Collars or stop pieces, *m*, *m'*, may be employed to limit the extent to which the intermediate shaft can be raised or lowered. An additional cam-shaft, *n*, running parallel with the main cam-shaft, *b*, on the opposite side of the cylinders is employed for operating the valves, *p*, to admit and cut off the compressed air or gas supplied to the cylinders through the pipe, *r*, for starting the engine. This auxiliary or starting cam-shaft, *n*, is rotated at the same speed as the main cam-shaft, *b*, by means of a chain driven from the main cam

shaft, *c*, driven from the crank-shaft, *a*, by skew-gear wheels, *d*, *e*, which intermediate shaft drives the cam-shaft, *b*, by bevel or mitre wheels, *f*, *g*. The intermediate shaft, *c*, passes through two bearings, *h*, *h'*, between which bearings is situated the skew wheel, *e*. The boss of the wheel, *e*, has a fixed key on projection, *c'*, engaging a keyway or recess, *c'*, formed in the intermediate shaft, *c*. By raising the shaft, *c*, rotary movement is therefore imparted to it independently of that derived from the wheel, *e*. The intermediate shaft on being raised passes through the bevel wheel, *f*, but being keyed thereto by means of a feather key, causes the bevel wheel to rotate with it, such rotary movement being conveyed to the cam-shaft, *b*, which is moved through the angle required to set the cams in the proper position

shaft, *b*. The rotation of the shaft, *n*, causes cam, *p*, thereon to press against pawls, *x*, *x'*, secured to bell-crank levers, *x*, and thus open valves, *p*, to admit the compressed air or other gas from the pipe, *r*, at a pressure of, say, 50 or 100 pounds per square inch, thereby moving the pistons of the engine downwards, such air pressure being cut off by the closing of the valves before the end of the piston stroke. The pressure from the pipe, *r*, enters through a port, *r'*, which opens into the centre of the valve seating, and in order to prevent the starting pressure from blowing the valves open, the valve stems are made with an enlargement, *y*, of the same area as the valve heads, so that the pressure on the back of the valve head and on the enlargement is equal. —October 4th, 1905.

24974. 17th November, 1904. Variable Speed Gear. Budapesti Malomépítész és Gépgyár Podvinecz és Heisler, Váci ut 141, Budapest, Hungary. This invention relates to variable speed gear adapted for use with automobiles and lathes. A drum loosely mounted on the driven shaft and connected with the driving shaft by means of a belt, chain or toothed gearing has secured within it a worm pivotally mounted on its own axis so that on rotation of the drum the worm is turned in the direction of rotation, and by means of separate mechanism also rotated round its own shaft or axis, a worm wheel meshing with the worm and fast on the driven shaft being turned in inverse relation to the speed of rotation of the worm. By means of the variable adjustment of the speed of rotation of the latter the driven shaft may be rotated at different speeds and even brought to rest. There are four figures. Fig. 1 is an elevation with the cover of the drum removed. Fig. 2 is a cross section. In the interior of the drum, 2, connected with the driving-shaft by belt, chain or toothed gearing, and loose on the driven shaft, there is secured a worm, 4, carried in bearings, 3, which meshes with a worm-wheel, 5, keyed on the driven shaft. Beneath the worm, 4, in radial direction, is a shaft, 6, rotatably mounted in the interior of the drum, 2, which shaft, 6, carries a small friction wheel, 8, adjustable in axial direction. In contact with this wheel is a friction disc fixed on the frame of the machine and having the driving-shaft passing through it along which it is adapted to slide. The shaft, 6, and worm, 4, are connected by transmission gearing, 10, 11. If the drum, 2, is rotated in the direction of the arrow, 12, the worm, 4, is also turned in the same direction. If there were no connection between the worm, 4, and the shaft, 6, then in the rotation of the drum, 2, the worm-wheel, 5, and also the driven shaft would be rotated by the worm, 4, in the same direction and at the same velocity. In the rotation of the drum, 2, however, the friction-wheel, 8, rolls on the face of the friction-disc, 9, whereby the shaft, 6, and also the worm, 4, are rotated around their own axes, so that the movement of the worm-wheel, 5, and of the shaft, 1, is retarded, the retardation depending on the speed with which the worm is rotated on its axis by the friction-wheel, 8. By moving the friction-wheel on the shaft, 6, the speed of the driven shaft, 1, can be regulated independently of that of the driving shaft, and the driven shaft can be brought completely to rest. The sliding movement of the friction-wheel along its axis can obviously be effected by any suitable means. —October 4th, 1905.

PASSING EVENTS.

"Audiatur et Altera Pars."

EVIDENCE has already been tendered before the Royal Commission by representatives of the leading automobile official organisations, including the Chairman of the Automobile Club and the Motor Union, and by the Secretary to the Joint Committee of the A.C.G.B.I. and the Motor Union, and now the body which has arrogated to itself the misleading title of the Highways Protection League, but which, as our readers are well aware, is an anti-automobile association pure and simple, is endeavoring to do what it can to influence the opinion of the Commission in an anti-automobile direction. We have not very much fear of the result. The Highways Protection League has for a long time past shown itself, both in its general proceedings and methods of action, to be so one-sided and so incapable of estimating the true

elements of the present situation, that anything which they or their members can have to offer in the way of evidence before the Royal Commission, can scarcely fail to benefit the automobile cause by its very contrast with the cogency and uncontrovertible character of the evidence which has been collected by the Joint Committee on behalf of the automobilist cause. So we trust they will all be heard, and heard at the length which they no doubt desire. It is doubtful indeed whether most of the people which the League calls upon to tender their evidence to the Commission, have any *locus standi*, or whether the Commission would in any way be bound to hear them. But we hope they will be heard. We should be very sorry if, considering the elaborate weakness of the case which the League has prepared, it should not be placed before the Commission. It would be nothing short of a misfortune that the Commission should only hear the situation from one side. In that case they might be disposed to think that there were arguments of some cogency on the other side, but that they had not heard them. All that we desire is that the Commission should have an opportunity of thoroughly investigating the relative merits of the automobile and anti-automobile points of view, and this the Highways Protection League is evidently bent on giving them. May they continue their activity on the lines they have hitherto adopted, till the automobilists' case is won. After all, they are our most convincing assistants.

◆ ◆ ◆ Injustice Coming Home to Roost.

THE very sensible determination of Mr. Leycester Barwell to refrain from contributing to charities, local or otherwise, in consequence of the large sums in which he has been mulcted for the merely technical offence of slightly exceeding the speed limit of motor cars, has been followed by other automobilists, and is bearing fruit of the most satisfactory kind. The action is being noted by the Society papers, and we have received one quite acidly-written paragraph from one of them intended to show that this course of action is everything that it ought not to be. We refrain from quoting the somewhat exuberant adjectives which our elegant contemporary has employed in this connection. But the general argument is that a great injustice is being done to the previous recipients of charity by the action of the automobilists who now refrain from further contributions. Well, it is a new argument that charity is an indefeasible right which the opulent possessor of property has no justification for refusing! But let that pass. Even the pockets of those reputedly wealthy people who are enabled to maintain automobiles (many car-owners, goodness knows, are far from being able to boast of excessive opulence) are not inexhaustible. If they are fined once a month or oftener, to the extent of £5 or more in costs, this will represent an increased expenditure of from £60 to £100 or more per annum, according as the victims elect to defend their cases or not. And £100 a year in charity is as much as the average man with a couple of thousand a year can afford to spend. If this £100 a year is being exacted in magisterial fines for merely technical offences, which, in point of fact, do no harm to anybody, it is no great wonder that the well-springs of charity become dried up. The important point, however, is that the decision of these automobilists is exciting attention, and that is the main thing. People are beginning to recognise that persecuting well-to-do members of the community, in the way to which we have become painfully accustomed, may produce unpleasant

reflex effects; and when that fact is established a considerable step is gained. The public will then be wakened out of passive acceptance of the position that all automobilists should be outside the pale of common justice with certain sections of the "great unpaid," and it will then begin to dawn upon the public that if this sort of thing is allowed to go on much further without check, it may bring about results in unexpected directions which may even ultimately reach them, and affect directly or indirectly their personal interests. We think, therefore, in the first place the thanks of automobilists are due to Mr. Leycester Barwell and others, and in the second place due to those papers who have become so angry at their attitude.

◆ ◆ ◆ Improvements in the Divisional Court.

It would certainly seem that the wave of enlightenment which appears to be affecting the country generally, with the exception of a few Benches of magistrates, is producing its effect on the Divisional Court. At any rate we think we are justified in drawing this conclusion from the recent case in which the Lord Chief Justice with Justices Wills and Darling as coadjutors, has entered a rule *nisi* for a writ of *certiorari* to issue against the justices of the borough of Bedford. The rule was applied for on behalf of Mr. Hindley Jenkins, who had been convicted by the Bedford Bench on the usual charge of driving to the danger of the public, &c., on the ground of biased prejudice on the part of one of the magistrates, viz., the Mayor of Bedford, Mr. H. Burrige, who was one of the magistrates who tried the case. There appears to have been a *prima facie* case for the contention of prejudice. It is not too much to say that Mr. Burrige's tactics appeared to combine in the well-known Irish phrase, the functions of "judge, jury, and persecutin' counsel all in one." Mr. Burrige had "laid the information" which led to the proceedings, and had then sat on the Bench with the other magistrates, retired with them to consult, and, therefore, apparently assisted in all ways in coming to a decision on the case. On hearing these facts, the Divisional Court decided to grant the rule asked for. We submit that this is a proof that the Divisional Court is becoming more enlightened, as our readers will call to mind that there were some years ago a couple of similar cases, in which the grossest bias, on the part of the magistrates trying them, was clearly shown, but a similar application for a *certiorari* was refused on the extraordinary ground, it will be recollected, that magistrates might be prejudiced against motorists, but so they were against *poachers*, and no one, according to one of the learned judges, ever heard that prejudice against poachers was a ground for impugning justices' decisions. We have travelled some distance it would seem, even in the Divisional Court, in the last two years. It is well to know that their Lordships seem no longer to regard motorists as on a precise level with poachers.

◆ ◆ ◆ Nothing like Leather.

EVERYTHING that can be made of leather is to be seen at the Annual Shoe and Leather Fair, held this week at the Agricultural Hall, the only things not made of that universal commodity being the instruments of the brass band, which discourse sweet music to the visitors, and the glasses out of which they quaff their beverages. It is satisfactory to find that the British leather trade is thoroughly holding its own. There was a great outcry at one time about the effects which the motor car industry was having, or was likely to have, upon it.

With the anticipated rapid extinction of the horse, it was supposed that the great demand for saddles for riding the horse, harness for attaching him to his duties, and whips for persuading him to proceed at a reasonable pace, would all be at a discount, that leather sellers and manufacturers would be bankrupt and that pigs and other quadrupeds which supply the commodity, would, in market language, be "looking up" or walking about with broad smiles on their faces. It is most satisfactory to learn that this terrible anticipated crisis is as far off as ever, and that, so far from annihilating the leather trade, the automobile has proved its greatest friend. This is due, not only to the large quantities of leather required for upholstering the bodies of cars, but to the enormous demand for leather which its employment for motor car clothing of all kinds, both for men and women, is evoking. In fact, high-class leather clothing is now being made by some of our leading English manufacturers from entirely British materials and with home labour, in as many as 300 different tints, some of which, at any rate, are calculated to appeal to the most artistic or fastidious eye. This happy state of affairs is one of the many proofs of the old saying that "of all mistakes which we can commit, that of prophecy is the most gratuitous." It is particularly gratuitous in the case of pessimistic prophecies regarding the effects of a new industry.

Getting out of it.

WE gather that the price of hemp has gone up in nearly all the districts over which the London County Council exercises its sway. The reason is that owing to the increase in rates due to the proceedings of that body, the ratepayers who find themselves unable to meet the demands are hanging themselves, wholesale. There have been several of these sad cases in one week and altogether the thing is far from a joke. There can be no question that the enormous outlay of the Council on the electric tramification of London, and the enormous immediate increase in the rates which has resulted, has had a great deal to do with it. Some considerable time ago when the motor 'bus first appeared upon our streets, we uttered a word of warning to the County Council in regard to the line they were adopting. As the motor 'bus develops, the cost of installing these expensive tramways is not in any way diminished, but their earning capacity is being distinctly impaired. If the wholesale expenditure in tramification had been incurred some ten or fifteen years ago, when the principal Continental towns adopted the electric tram, there would have been little or nothing to urge against it. London would then have been abreast of general progress, and, instead of its means of locomotion exciting the amused sympathy of foreign visitors, they would, at any rate, at that time have been up to date. Now, however, things are totally different, and the Council's proposals amount to inviting, or, rather, compelling, the heavily burdened ratepayer to sink millions in a form of locomotion which everything shows is likely to be quickly superseded, or, at any rate, largely deprived of its earning capacity. Now, therefore, any chance of the Council seeing the money of their ratepayers back again is much more remote. The influences which have determined the controlling spirits of the Council to sanction these contracts and this enormous expenditure of course still remain, but that the ratepayers put up with the situation is one of those mysteries of complaisance which nobody but the absolutely complaisant will be able ever to fully comprehend.

Tramcar Speeds.—The Automobile Club has been compiling statistics to show the speed of electric trams in different towns throughout the kingdom. The high speeds registered will not surprise anyone who has observed at all carefully the pace at which electric trams career along in defiance of the Board of Trade, and go to show, as we have always contended, that 20 miles an hour is not by any means an out-of-the-way speed for an electric tramcar when it gets a clear stretch of road. There can be no doubt about the correctness of the times noted, as they were taken by Mr. T. H. Woollen, M.I.Mech.E., F.S.A., head timekeeper (honorary) to the Automobile Club, and timekeeper to the National Cyclists' Union. A summary of the results obtained is as follows:—

Summary of Speeds of Electric Trams in Certain Towns.

Town.	Distance over which Timed.	Number of Cars.	Average Speed of		Speed of Fastest Car.
			All Cars Timed.	Six Fastest Cars.	
	yards.				
London (Streatham Hill)	110	22	18'95	20'45	21'22

Motorist Persecution Bearing Fruit.—A drastic revolutionary writes to one of the morning papers, and he has positively the hardihood to propose the curtailment of the powers of the "great unpaid." He suggests that these functionaries should in future be employed for services for which they are fitted, viz.:—

- (1) The signing of official and post-office declarations.
- (2) Administration of oaths.
- (3) Granting and signing summonses.
- (4) Hearing cases for remand purposes only, with power to dismiss the case.

while the administration of justice should, in his opinion, be in all cases exercised by paid public functionaries similar to stipendiary magistrates, whom he would prefer to call "petty judges." Such an official would be a great improvement, he thinks, upon the magistrates' clerk, who at present is "an unsatisfactory combination of public prosecutor, cross-examiner, and Bench," and would be but little more expensive. This scheme, in fact, is almost identical with the system prevailing in Germany.

THE Municipal Technical School of the city of Liverpool has organised a series of lectures on Motor Car Engineering, which are to be delivered by Mr. G. B. Mercer, A.M.Inst.C.E., head of the firm of Robinson and Price, of Liverpool. The first lecture, which was delivered on Wednesday last, was a conspicuous success, as many as 70 students attending, and there is every reason to suppose that a successful series of lectures will be held.

VANDERBILT CUP RACE.—Another remarkable and interesting view of the course, at the Grand Stand, a few minutes after the completion of the race, when the public had broken on to the roadway.

VANDERBILT CUP RACE.—In connection with the allotment of numbers in this race, it was suggested that No. 13 should be skipped, superstition against getting good luck behind this number being somewhat pronounced amongst the competitors. This suggestion was, however, not acceded to, and to get over the difficulty, Campbell who had No. 13 allotted to him, and who drove the 120-h.p. Mercedes on behalf of Germany, denoted his car by the sign "X," as seen in our photograph; No. 14, and the remainder of the cars still to be sent off, are ranged behind, ready for their call.

HIGH-TENSION MAGNETO IGNITION.—PART XIV.

BASSÉE-MICHEL SYSTEM (1906 MODEL).

(Continued from page 1320.)

The Low Tension Gear.

It has already been mentioned that one end of the armature coil, C, is connected to the slip-ring, C¹. From

this ring the electricity is collected by means of a carbon brush, C⁴, which projects through a slot in the bearing-plate, M¹. This brush is carried in a small tube, or brush-holder, C⁵, which contains a weak spring for gently pressing the brush against the slip-ring as the armature revolves. The position of this brush, and the manner in which it is carried, are indicated in Figs. 2 and 5, and it will be noticed in Fig. 5 that the brush-holder is provided with a screw-cap which enables the brush to be removed, when necessary, without trouble.

The brush-holder is not fixed directly to the front bearing-plate, M¹, but to another plate, K⁴, which is free to move independently. This plate, K⁴, which is shown separately in Fig. 4, carries all the contact-breaking mechanism, which is visible in the lower part of Fig. 5—with the exception, of course, of the cam, B⁴, which is mounted on the end of the armature spindle, B¹. The plate, K⁴, is mounted about a boss on the bearing-plate, M¹, and is retained in that position by means of a spring, K⁵, and slotted washer, K⁶. This method of fastening—which is clearly indicated in Fig. 5—is very simple and effective; by removing the washer, K⁶—which is used on the principle of a bayonet-socket fitting—the plate, K⁴, can be instantly removed. The reason for mounting the plate, K⁴, independently, in the manner described, is in order to enable it to be rocked about its bearing; this being the method adopted for "timing," as will be explained presently.

On the same fitting which directly carries the brush-holder, C⁵, is the terminal, C¹², which is thus virtually the live end of the armature-coil. Both the terminal, C¹², and the brush-holder, C⁵, are, of course, carefully insulated from the plate, K⁴. A wire is led from this terminal, C¹², through the switch, to the induction-coil—which will be described later—and another wire leads the electricity back again direct from the induction-coil to another terminal, C¹³, on the magneto.

The terminal, C¹³, is also insulated from actual metallic contact with the plate, K⁴, but it is electrically connected with the small bracket which carries the adjustment-screw, C⁷, forming one part of the contact-breaker, C³. The other part of the contact-breaker is formed by the bell-crank lever, which is operated by the cam, B⁴. As the bell-crank lever is electrically connected with the plate, K⁴, which forms an "earth," the terminal, C¹³, is thus equivalent to the "earthed" end of the armature winding, so long as the two points of the contact-breaker, C³, are held together. Directly they are separated, however, the electrical circuit from the armature, through the low resistance primary winding of the induction-coil, is broken; and it is at this instant that a

spark occurs at one of the ignition plugs on the engine. In order to ensure an entirely satisfactory connection between the armature core and the magneto frame, a carbon brush—which forms part of the lubricator—is

FIG. 4.—The Bassée-Michel High-Tension Magneto (1906 Type).—View of the front Bearing Plate, M¹; also separate views of the principal component parts of the High- and Low-Tension Mechanisms.

arranged to press against the driving end of the armature spindle.

The Induction Coil and Condenser.

In most cases it is usual for induction coils to be constructed complete with their own condensers, but in the

on the magneto, but the wire leading from T^1 to C^{12} passes through the switch. Of the other two terminals, D^1 , is the "live" end of the secondary or high-tension winding, and, E , is the other end of the same winding which is "earthed." This terminal, E , is also common to that primary coil which has its other end connected to the terminal, T^1 .

Connected to the terminal, D^1 , is a strip of metal projecting towards the terminal, E . The space, D^2 , between these two members forms a safety-spark-gap for the protection of the coil in the event of a fault in any part of the external high-tension circuit. Should, for instance, one of the wires leading to an ignition plug be broken, a spark will, in all probability, occur at D^2 , but in any case the width of this gap is such that a spark will pass if the voltage is greater than is safe for the insulation of the coil. A sheet of mica is placed beneath the gap, D^2 , in order to protect the case.

The condenser is rather larger on this than on most machines, and it is retained in position by the bearing plates, M and M^1 . One side of the condenser is, of course, "earthed," and the other is provided with a terminal by which it can be electrically connected to the contact-breaker. The strip of bent brass, F^3 , by which this connection is made, is prominent in Fig. 3, and the manner in which the connection is maintained by means of the contact, F^5 , and spring, F^7 , for all positions of the plate, K^4 , is clearly shown in Fig. 4. The spring is connected to the terminal, C^{13} , and the contact, F^6 , to the connector, F^5 ; both being, of course, efficiently insulated.

This form of construction is adopted in order to obviate the necessity, which would otherwise exist, for connecting up the condenser by a flexible wire.

(To be concluded.)

FIG. 5.—The Bassée-Michel High-Tension Magneto (1906 Type).—View showing, on a large scale, the mechanism carried by the Bearing Plate, M^1 , which is illustrated in detail in Fig. 4.

Bassée-Michel system these are made as separate units. The induction coil, which is illustrated in Fig. 1, is contained in a box, and the condenser is enclosed in an aluminium case, F^3 (Fig. 2), which is accommodated in the space, between the limbs of the magnets, above the armature. The condenser is thus in close proximity to the contact-breaker, whether the magneto or the battery is in use—the importance of which will have already been recognised by our readers.

The general construction of both these members is not different from that usually employed, and as they are not intended to be dismantled by the motorist, it is unnecessary for us to give any detailed photographs or description of their interiors. Nor would such illustrations show anything more than a coil of wire in the one case, and a bundle of tin-foil and paper in the other.

On the outside of the case containing the induction coil, there are five terminals, and one of these, T^1 , is connected through the switch to the accumulators. Two others, T^1 and T^3 , are connected to the terminals, C^{12} and C^{13} ,

FIG. 6.—The Bassée-Michel High-Tension Magneto (1906 Type).—Diagram of the Internal Electrical Connections. The reference letters employed in connection with this illustration are the same as those used throughout, and this diagram has been prepared so that the system may be readily compared with others already described.

THE 1905 ARGYLL CARS.—PART IV.

(Concluded from page 1323.)

The "Govan" Change-Speed-Gear.

No other portion of an Argyll chassis differs more from the corresponding part of other cars than the change-speed mechanism, for the "Govan" gear is quite unlike that employed by any other maker. It is, however, similar to the orthodox pattern, up to a point, and, indeed, at first sight, little unusual might be noticed about it. Its particularly strong points are that no spur-wheels need be slid into mesh with one another while they are revolving, that either of the three forward speeds can be introduced without it being necessary to bring an intermediate speed into play when doing so, that both shafts are extremely short, that a direct-through drive is

a view from above, and to the right is a side view and an end view. Fig. 20 shows, on a larger scale, an important portion of the mechanism that introduces the second and third speeds.

The driving-shaft, K—which is connected with the clutch-shaft (J) by a flexible coupling—is rigid with the spur-wheel, K¹, and this wheel has jaw-clutch members formed on its inner face. The wheel, K¹, is always in mesh with the larger spur-wheel, K², on the lay-shaft, K³, and, thus, that shaft always revolves at a slow speed whenever the clutch is "in" and the engine running. Also rigid with the lay-shaft, K³, is the spur-wheel, K⁴, at the other end, and this wheel is at all times in mesh with the wheel, K⁵, which normally rides idly upon the

Fig. 18.—Three views of the "Govan" change-speed-gear, employed on all Argyll vehicles. On the left, the interior of the gear-box is seen from above, and the upper half (inverted) together with its bolts and yokes are arranged alongside. On the right, the complete mechanism is shown from the rear, and the front, respectively.

obtained on the top gear, and that the lay-shaft runs at a comparatively low speed.

Reference to Figs. 18, 19, and 20 will enable its construction and the arrangement of the operating mechanism to be followed. To the left, in Fig. 18, it is seen from above, with the upper half of the box removed and arranged alongside to show the interior. Here, too, will be noticed the four bolts and two yokes by which the two halves of the box can be firmly and quickly clamped together. To the right, in the same illustration, are views of the complete gear-box from either end. The four photographs reproduced in Fig. 19, not only show the gear-box fixed in place, but also give an excellent idea of the operating mechanism. To the left is a view from beneath, while, in the centre, is

"driven" shaft that carries the brake-drum, M³. The wheel, K⁴, always revolves at two-thirds the speed of the wheel, K¹, and it has jaw-clutch members on its inner face. So far as the second and third speeds are concerned, it only remains to explain that the "driven" shaft, at its forward end, takes a bearing inside the "driving" shaft, K, and that its centre has a square cross-section for the spur-wheel, M, and its jaw-clutch faces, to slide upon. This sliding member locks the driven-shaft either with the wheel, K¹—to give the direct third speed—or with the wheel, K⁴, to give the second speed, according as to whether it is slid forwards or backwards.

A square cross-section is also given to the lay-shaft, K³, and, upon it, rides the comparatively small spur-wheel, L¹, which can thus be brought into gear with the

Fig. 19.—Four views of the "Govan" change-speed-gear, complete with its operating mechanism. On the left, it is seen from beneath; in the centre, from above; and, on the right, it is shown from the "near" side, as well as from behind.

spur-wheel, M, to give the slow-speed first-gear; the wheel, M, when driven by the wheel L¹, revolves at one-third the speed of the wheel, K¹. Since this "speed" need never be introduced except for starting the car from rest, the wheels, L¹ and M, are slid into mesh with one another *before* they commence revolving. For giving the "reverse," the wide intermediate pinion, N², is provided inside the upper portion of the gear-box, and is carried on an eccentrically-mounted pin, N⁴, that can bring it into mesh with the wheels, L¹ and M, when the pin is rocked about its axis.

Both the sliding members of the change-speed-gear are controlled by the same hand-lever, L, although two entirely distinct connections are made between it and them for this purpose. The sliding member, L¹, is coupled up to the bell-crank, L², as seen in the illustrations, and this is, in turn, connected to the bottom of the lever, L, by the rod, L³. To operate this portion of the gear, the lever, L, is hinged by the pin, L⁴, to its rock-shaft, with the result that it can be moved outwardly (away from the side of the car) and does not then rotate the rock-shaft. This movement in the three-way quadrant merely slides the first-speed spur-wheel, L¹, into mesh with the wheel, M. At both ends, the rod, L³, has ball-joints to allow the hand-lever, L, to be moved forward or backward in its quadrant—movements which do not affect the first-speed mechanism.

For the second and third speeds, the sliding wheel, M (with its clutch jaws) is similarly controlled by a bell-crank lever, M¹, but this is engaged by the lever-arm, M², that projects down from—and is rigid with—the rock-shaft of the hand-lever, L. By moving the hand-lever forward, the wheel, M, is caused to engage with the wheel, K⁴, by virtue of their jaw-clutch members, and by moving it backward, that wheel engages in the same manner with the wheel, K¹—giving the third speed, as against the second speed in the former case. At the top of the lever, L, is a spring-catch handle, and this controls a locking-pin which engages with corresponding slots in the quadrant, and thus retains the lever in either of its working positions.

An important feature of the mechanism connecting the lever, L, with the second and third speed jaw-clutches has purposely escaped attention in the foregoing paragraph, since its action and utility will be more easily comprehended now that the functions and arrangement of the other parts have been explained. It is evident that the jaw-clutch members may at times fail to be exactly opposite one another when the lever, L, is moved, and that, therefore, they would be unable to engage with one another immediately. Inconvenience would arise—and possibly injury to the gear also—if the hand-lever had to be held until such time as the jaw-clutches could come into

Fig. 20.—An important portion of the "Govan" gear, as fitted to the Argyll Cars; this simple device not only saves the jaw-clutches from being injured by a careless driver, but enables the gear-lever to be moved into its second or third speed position at any time without waiting for the jaw-clutches to come into engagement.

operation, and, therefore, the very ingenious device shown on a larger scale in Fig. 20 is fitted. It is introduced—as seen on the left in Fig. 19—between the bell-crank, M^1 , and the sliding rod, M^4 , and permits the gear-lever, L , to be moved at any time from one position to another. A second bell-crank, M^3 , is pivoted to the same fulcrum-pin, M^4 , as the bell-crank, M^1 , but both ride independently of one another about the pin. The latter has, however, two small forgings, M^7 , pivoted to it at M^6 , and these forgings are forced together so that they grip one arm of the bell-crank, M^3 , between them. Two springs, M^8 —one above and the other below—serve to give the necessary pressure, and it is these springs that allow the bell-crank, M^1 , to be moved by the hand-lever, and permit the other bell-crank, M^3 , to delay in following suit until later. In Fig. 20, in which this mechanism is seen from below, the lower spring has been partly removed in order to show the forgings, M^7 , and only small portions of the upper spring are visible beneath those forgings.

Little explanation is needed concerning the reversing gear, in view of the very clear manner in which the entire mechanism is shown in our illustrations. It is operated by the hand-lever, N , which is coupled up to the eccentric pin, N^4 , by the rod, N^1 , and the bell-crank, N^2 . The hand-lever itself is solid with a short projecting arm, N^3 , (Fig. 19, left hand photo), and it is this arm that engages with the bell-crank, N^2 .

Concluding Remarks.

Such then are the more important details of construction adopted in this year's Argyll cars, concerning the general excellence of which we have already also spoken. Certain other parts, such as the foot-brake, the ratchet-sprag, and the propeller-shaft, have not been dealt with minutely because they do not differ materially from those employed on other well-known makes of chassis, and because their nature is well demonstrated in one or other of our numerous illustrations. It is sufficient, therefore, to say that each of them is quite in keeping with the

character of the chassis as a whole, and that they possess the same simplicity of design and suitability for the work they have to perform, as do those portions of the mechanism to which we have given our chief attention in this somewhat lengthy article.

AERONAUTICS.

Lebaudy Airship Triumphs.—The Lebaudy airship continues to give demonstrations of its serviceability for military purposes, and on the 24th inst. it took up the Minister of War, M. Berteaux, to survey the defences in the neighbourhood of Toul. The Minister of War was received by Messrs. Julliot and Paul and Pierre Lebaudy on Monday last at Toul, and the whole staff of the Aeronautical Department were in attendance. The airship was brought out from the shed belonging to the 39th Regiment of Artillery, and after the formal introduction of its owners and engineers to M. Berteaux, the Minister expressed a desire to make a tour with it, in spite of the north-east wind, which was blowing at some fifteen miles an hour. M. Berteaux entered the car accompanied by Commandant Gossard, Commandant Bouttiaux, Capt. Voyer, head of the Aeronautical Department, M. Georges Juchmès and M. A. Rey. Altogether the airship took up six passengers and 300 kilos. of ballast, together with sacks of sand of 10 kilos. intended to represent the weight of possible projectiles. The airship carried on evolutions from three o'clock till half-past three, circling over the forts and works of Toul. The Minister of War satisfied himself of the possibility of dropping bombs with precision on indicated points, and was most enthusiastic in his praise of the efficiency

of the manoeuvres. The entry to the shed in which the airship is accommodated was made without difficulty at the end of the return journey. This official recognition of the military value of the Lebaudy airship has naturally attracted attention to its designer, M. Henry Julliot, who deserves the greater part of the credit for its successful performances. He was for a considerable time employed in Messrs. Lebaudy's sugar refineries, and it is only in recent years that M. Julliot has taken up the engineering and construction of airships.

THE great airship of Count Zeppelin, on the lake of Constance, which has been rebuilt and made a trial run, as we chronicled some time ago, is now again ready for experiment, and at present accommodated in the great shed which floats on the surface of the lake. Considerable alterations have been made in this airship from the machine which originally (before the days of Mons. Santos Dumont) performed evolutions above the lake. The present gas-vessel is 400 feet by 40 feet in diameter, and is divided into 20 gas-tight compartments, the whole being trussed and held together by an interior framework of aluminium rods, rings and wires, the exterior covering being of pegamoid, which has shown itself singularly unaffected by adverse atmospheric conditions.

THE 1906 OLDSMOBILES—SOME RADICAL INNOVATIONS.

The 20-h.p. Oldsmobile Car, which is the larger of the two 1906 models having vertical engines and live-axle transmission mechanisms. The 20-h.p. Motor has four cylinders.

OLDSMOBILES so instinctively suggest an extremely popular type of light car that is sold at an extremely low figure, is the essence of simplicity to drive, and has deservedly earned a world-wide reputation in its own particular field, that it will doubtless take time for the average motorist to recognise, as Oldsmobiles, the new 12-h.p. and 20-h.p. models which are now being introduced by the enterprising American builders of these cars. These additional types, which will be shown to the British public for the first time by Messrs. Jarrott and Letts at Olympia this month, are designed on essentially European lines, and differ, in fact, only in constructional details from ordinary orthodox cars of the live-axle type. Naturally, however, they are not in any way intended to replace the earlier, and comparatively low-powered, "run-about" pattern, which—on the contrary—has once more been greatly improved in many important respects.

The Powerful New Models.

The two larger models are similar in design, both

having vertical engines beneath the bonnet in front, main clutches of the cone variety, change-speed-gears of the sliding spur-wheel pattern—giving three forward speeds and a "reverse"—and propeller-shafts to transmit the power to their driving axles. In both, moreover, the specially-constructed channel-steel frame enables the engine to be drawn out direct in front, if at any time it has to be removed, and there is a sheet metal shield fixed to the frame beneath the engine and the gear-box.

The 12-h.p. engine has, however, a pair of 5 in. bore by 5 in. stroke cylinders, whereas the 20-h.p. model has four cylinders of $4\frac{1}{4}$ in. bore by $4\frac{3}{4}$ in. stroke.

Our illustrations give a good general idea of the appearance of these vehicles, but it should be specially noted that the standard 12-h.p. has a considerably longer wheel-base than the 2-seater shown in the photograph, and that it is normally provided with a detachable tonneau body. Both chassis are designed to take side-entrance bodies; the larger car comfortably accommodates five persons.

View of a twin-cylinder 12-h.p. Oldsmobile Car, similar to the standard new model, but having a shorter chassis; usually this type of vehicle has a detachable tonneau body to seat four persons.

Amongst other interesting features should be mentioned the lubricating system adopted on these new cars, for the oil is forced by a gear-driven pump to all the bearings, including those of the transmission-gear as well as the engine. The circulating pump for the cooling water is also positively driven by gear-wheels, the levers controlling the engine are mounted above the steering wheel, and the semi-elliptic side springs are all sufficiently long and flexible to ensure comfortable travelling.

The Improved "Run-about."

Outwardly, the 7-h.p. "run-about" resembles those of this year, but many parts of the vehicle and its mechanism have undergone considerable modification as the result of the further far-reaching experience of the past year; good as any such machines may be, it is but natural that further improvements can continue to be made. The brakes, in particular, have received attention, with the result that the old differential-brake has been replaced by one of an entirely different character, and that the design of the external hub-brakes has been modified; the brake-bands, as also those which form a part of the change-speed mechanism, are lined with camel-hair belting. In connection with the axles,

changes have been made, the front-axle being stronger, and the back-axle having radius-rods that render it impossible for the driving-chain to come in contact with the axle-casing. The springs, too, are considerably more flexible, and the live-axle has easily-replaceable bushes for the "Hyatt" roller-bearings with which it is fitted.

The engine has also been modified in some respects, notably in means for facilitating starting in winter, and in having an automatic lubrication system. The connecting-rod no longer has a hinged cap, the piston now has an additional ring at the front end, the valves and valve-gear are altogether stronger than formerly, and a very much larger pump is used for the cooling water. The pump is, by the way, driven by a silent chain from the crank-shaft.

We have not as yet been able to inspect these new Oldsmobiles personally, but it is evident from the foregoing information that the "run-about" is bound to appeal even more forcibly than before to those requiring a really satisfactory and cheap little vehicle, and it almost goes without saying that the larger models will appeal to a large number of purchasers; naturally they, also, are being turned out in such a manner—on a very large scale—as to be sold at a low price.

THE 1906, 22-28-H.P., CROSSLEY CAR.

* Fig. 1.—The new 22-28-h.p. Crossley Chassis. View from the "near" side, showing the manner in which the wheel-base has been lengthened, and the general disposition of the entire mechanism.

FOLLOWING up the general information which we gave last week concerning the 1906 Crossley models, we are now able to reproduce three photographs of the new 22-28-h.p. chassis. The first shows it complete from the near side, the second is a view from the rear, and the third gives an excellent idea of the new gear-box. We are also able to supplement what has already been said, with some further particulars of this well-designed and good all-round vehicle.

A noticeable feature is that very long spring-hangers are fixed to the frame at the rear, with the object of bringing the driving wheels well back,

although the frame itself is not lengthened. The front wheels, also, are carried considerably forward of the engine, and thus the full advantages of a long (10 ft.) wheel-base are secured. In outward appearance, the engine, with its cylinders in pairs, its valves on opposite sides, and its low-tension magneto-ignition, remains but little altered, although, as pointed out last week, it has undergone many important improvements of a minor character. The lubricating system is fed by pressure from the cylindrical tank, placed outside the frame, as seen in Fig. 1, and a simple sight-feed lubricator on the dashboard distributes the oil to the engine.

13th). Between the clutch and the gear-box, the longitudinal shaft has universal joints at both ends. Usually, neither the foot-brake nor the hub-brakes are interconnected with the clutch, but provision is made for connecting the latter with it when required. The hub-brakes, which are compensated by a steel cable, have the shoes fixed to a spring-steel expanding member, the ends of which are forced apart by small toggle-links; the spring-steel draws the shoes clear of the drum, when the brake is "off."

Considerable attention has been paid to the steering-gear, both to ensure strength and to render it smooth and easy in action. The steering-heads, which are of the internal type, have ball-bearings above and beneath the axle, and there is also a ball-thrust to take the weight of the vehicle. Another point is that the cross-rod, connecting the two steering-heads together, rests down upon the ball-sockets on the steering-arms, instead of being held up by them; this rod is, moreover, quite straight, and passes across behind the axle. A special form of adjustment is also provided for taking up all back-lash in the long rod that connects the steering-gear with the axle-mechanism.

As will be realised, the designers and builders of the Crossley cars have taken full advantage of the great progress made in the automobile and engineering worlds during the past year, and have applied their study of the many questions involved, both to their new 40-h.p. model, and to the further improvement of the 22-28-h.p. car as well.

Fig. 2.—View of the 22-28-h.p. Crossley Chassis, from the rear. In this illustration is seen the new Gear-box, the strong pressed-steel Frame and the powerful metal-to-metal Brake on the Countershaft.

Perhaps the greatest change will be recognised in the gear-box and in the operating mechanism, for this now follows closely on the well-known Mercedes lines, and is controlled in a similar manner. The gear-box itself is fixed direct to the strongly-constructed pressed-steel frame, and its sliding members are connected to the three rods that pass forward from it. The simple mechanism by which the change-speed-lever is brought into engagement with either of these sliding-rods, is enclosed in a dust-proof casing, and the quadrant in which the lever is moved forwards or backwards, to introduce either required speed, has three corresponding slots to receive it. Fig. 3 not only shows the interior of the gear-box, with the ball-bearings on all three shafts, but also the powerful metal-to-metal foot-brake on the differential countershaft. Comparatively little alteration has been made to the expanding clutch since early last year, when a very fully illustrated description of the 1905 chassis appeared in our columns (Jan. 30th, Feb. 6th and

Fig. 3.—The 1906 Crossley Gear-box, with the upper half removed to show the entire interior mechanism. In this view, the D.W.M. ball-bearings, the strong gear-wheels, and the sliding rods that introduce either of the four forward, or the "reverse" speeds, are particularly prominent.

THE "LLOYD" CHANGE-SPEED GEAR.

The "Lloyd" Gear for Petrol Cars.—View showing this novel form of mechanism, in which the "gear-wheels" have rollers instead of teeth; it is fixed to the pressed-steel frame of a chassis.

THE type of gear mechanism which the Quadrant Cycle Company are introducing for use on motor cars of all kinds is quite unlike that now fitted to any vehicle with which we are acquainted. It is not, however, an altogether new invention, and is, in fact, that which has been employed on the chainless bicycles made by this firm—one of which has, we learn, been ridden a distance of over 60,000 miles, and is still in good running order.

For automobile work, the "Lloyd" gear is constructed as shown in our illustrations, which represent it fixed in place to the pressed-steel frame of a chassis. The longitudinal shaft, A, is mounted so that it can be coupled up direct to an engine of any ordinary make, and is, for this purpose, placed in line with the crank-shaft of the engine (when fitted). Between its bearings, the shaft, A, has a square cross-section, and over these portions the peculiarly formed pinions, B and C, are free to slide; they can be moved backwards or forwards, simultaneously, by the change-speed lever, *after* the clutch-pedal—to which reference is made presently—has been depressed. The pinions consist of cages, each carrying six specially-shaped rollers—that act as teeth; the pinion, B, serves to give the four speeds forward, and the other pinion, C, gives a slow-speed "reverse."

The shaft, J, to which the power is transmitted from the shaft, A, lies transversely, and is provided at its inner end with the large driving disc, D. Projecting from the face of the disc are four concentric sets of rollers, E, F, G, and H, with either set of which the pinion, B, can engage. Each set of rollers thus forms a kind of

bevel-wheel, and it is they that give the four different gear-ratios. Special emphasis is laid on the facts that the hardened-steel rollers only present a mathematical "point" contact to one another—since they engage crosswise—and that, being free to revolve, they do not rub against one another.

For changing from one speed to another, and also for giving the necessary clutch action, the shaft, J, is fitted

Plan of the "Lloyd" Gear, arranged to give four forward speeds and a "reverse" between the engine-driven shaft, A, and the shaft, J—from which the power is transmitted to the live axle by a single chain.

so as to be free to slide lengthwise in its bearings, and, at its outer end, it is provided with a toggle-mechanism, J, that imparts this movement to it from the clutch-pedal. When drawn away from the shaft, A, the disc, C, ceases to engage with either of the pinions, B or C, and then these wheels can be moved along their shaft to a different position. The 1st, 2nd, 3rd, and 4th speeds, forward, result from bringing the pinion, B, into mesh with the rollers, E, F, G, and H, respectively, and the "reverse" speed is obtained when the pinion, C,

meshes with the outer set of rollers, E; there is a free position in which both pinions are entirely clear of the disc, D. In this form of the "Lloyd" gear, the power is transmitted by a single, "silent" chain, K¹, from the shaft, J, direct to the "live" rear-axle of the car. The sprocket, K, and the drum, L (for the foot-brake), ride on a square portion of the shaft, J, and do not therefore slide sideways with the shaft. Amongst the claims made for this type of change-speed-gear are efficiency, silence, and durability.

THE PNEUMATIC SUSPENSION WHEEL.

ALTHOUGH not literally a "spring" wheel, the "pneumatic suspension wheel" introduced by the Pneumatic Suspension Wheel Co., is nevertheless among that category of devices which are designed for the purpose of affording a resilient medium—if not of an unpuncturable material—at least in an unpuncturable place within the wheel. The principle of the "pneumatic suspension wheel" is that of arranging a pneumatic tyre around the hub, where it is in an isolated and easily-protected position, and where it can, therefore, be used in a less highly inflated condition than would be desirable in a pneumatic running in contact with the road.

to their respective rings. Between these two rings, A² and B², is a canvas-covered air-tube, C, which is inflated through the valve, C¹, in the same way as an ordinary pneumatic tyre. This air-tube tends to keep the two members, A² and B², concentric with one another when the wheel is in equilibrium, and to absorb the road shocks when the wheel is in use. The weight of the machine, which is carried by the hub, B, is transmitted by the spokes, B¹, to the upper part of the ring, B², which in turn transmits it to the inner ring, A², through the air-tube, C. The spokes are thus always in tension, as in an ordinary wire wheel. The air-tube, C, is not endless, like the inner tube of

The Pneumatic Suspension Wheel.—View of the wheel complete, but without the tyre, and view of the "pneumatic suspension" device, on the right. The air-tube, C, is not endless, but forms a sealed tube, which can be inflated at C¹, like an ordinary pneumatic tyre, and can be withdrawn—when deflated—from its position without dismantling the wheel.

The illustration shows, on the left, a motor bicycle wheel fitted with this device, but the tyre proper—which may be pneumatic or otherwise as desired—is not in place. On the right, is a larger view of the "pneumatic suspension," which shows the method of detaching the air-tube.

The spokes, A¹, of the rim, A, are connected at their inner ends to the ring, A², which, it will be noticed, is nearer the hub than the ring, B², to which the spokes, B¹, of the hub, B, are attached. The spokes, B¹, pass through slots in the ring, A², and the spokes, A¹, pass outside the ring, B², so as to enable them to be connected

an ordinary pneumatic, but is made in one length with sealed ends in such a way that it can, when deflated, be withdrawn from the rings, A² and B², through a slot cut in the ring, B², for that purpose. Should this tube become damaged through any cause, a new one can thus be easily inserted without dismantling the wheel.

A SILENCING CONDENSER FOR MARINE MOTORS.

WITH the three-fold object of scavenging the working cylinders of marine petrol motors, and of cooling and silencing the exhaust gases, the apparatus shown in our illustrations has recently been put on the market by Messrs. Rankin, Kennedy, and Sons. Into the chamber, B, which is slightly larger than the engine cylinder, the

nozzle. The gases and the water mix with one another, the former quickly giving up their heat to the latter—forming, it is claimed, an appreciably high partial vacuum—and both are finally led away, cool and silent, by the discharge pipe, O. Usually it is convenient to employ the cooling water passing from the cylinder-jacket for this purpose, but the necessary water may be drawn up direct by the apparatus itself—without the aid of a pump—if desired. The chamber, B, is found to

View of the Rankin-Kennedy Marine Silencer, fitted to a single-cylinder petrol engine.

Side elevation (part sectional) showing the Kennedy Silencer fitted, in a boat, to a petrol engine.

exhaust gases are led by the short pipe, E, and water is also admitted through the pipe, W. The gases issue through the nozzle, N, and the water is drawn as a spray through the contracted throat around the mouth of the

keep quite cool in practice, and, apparently, the power of the engine is increased, rather than decreased (as with most silencers) by the use of this simple apparatus.

1906 Minerva Cars.—The most important innovation on the new Minerva cars, which will be shown at Olympia, is the adoption of a live axle instead of the chain drive hitherto employed. Other important new features include a pressed steel frame, ball bearings in the gear-box, two ignition systems, and thermosyphon cooling. The chassis will be made in two models, viz., 16-h.p. and 22-h.p., and both will be fitted with four-cylinder engines.

Olympia Motor Show.—At this show, which opens on Friday, November 17th and remains open till the following Saturday, November 25th, there will be over 300 exhibitors, as compared with 248 at the last exhibition. By the enormous rush of applicants for space, the policy of holding the show before the Paris Automobile Salon in December has been fully vindicated, and the fact that the best Continental firms will be represented by their 1906 models in the exhibition must be a source of considerable satisfaction to the Society of Motor Manufacturers and Traders, who have brought their exhibitions up to such a splendid pitch of success. Continental firms have long since recognised that Great Britain is their best market, and whatever their patriotic feelings may suggest, their commercial instincts tell them plainly that they cannot afford to wait for the British customers to go to Paris, under the conditions of the Olympia Exhibition being held first. Fifty-one foreign firms are exhibiting, either personally or through their agents. Over 100 firms will show pleasure motor cars, 35 commercial vehicles, and 26 motor boats. In addition, there will be an enormous gathering of specimen carriage work, tyres, components, accessories, and machinery. The 10,000 feet additional space provided in the annexe, has enabled the Motor Boat Section to

be specially expanded, and it will probably form one of the most interesting features of the Exhibition. The scheme of lighting and decoration has been considerably extended, and will give even more brilliant effects than at the Show held in the earlier part of the year. Lieut. Godfrey's Orchestra will perform each afternoon and evening. Standing room for over 100 cars belonging to visitors is provided at the Hammersmith Road entrance to the Exhibition, and trial runs of exhibitors' cars can consequently be conveniently arranged. If any additional promise of success were needed, the fact that the King has for the first time accorded his patronage to the Exhibition, should make that success doubly assured.

The Society of Motor Omnibus Engineers, at the invitation of the exhibition organisers, will formally visit the Exhibition on Wednesday afternoon, November 22nd.

Royal Commission on Motor Cars.—At the seventh sitting on October 26th there were present Viscount Selby (chairman), the Marquis of Winchester, Sir D. Harrel, Sir W. B. Forwood, Mr. Monro, and Captain Bigham (secretary). The examination of Mr. Butterworth (representing the Highways Protection League) was concluded, and the following witnesses were heard: Mr. Alfred Mills, Secretary to the Federation of Associated London Cab Proprietors; Major A. F. Poulton, Chief Constable of Berkshire; and Major H. L. Lang, Chief Constable of Sussex. On Tuesday the following witnesses were examined:—Mr. Henry Hall, of Alphington (Exeter); Mr. T. H. Ryland, hon. secretary of the Midland Automobile Club; and the Earl of Shrewsbury, president of the Automobile Mutual Protection Association. The Commission met again on Wednesday.

CIRCLING THE GLOBE ONCE MORE.

"ENCIRCLING THE WORLD" BY MOTOR CAR.—The views given above depict some of the experiences of Mr. Glidden in Australia. 1, is a bad bit of road which he encountered, 2, is the southernmost road in the world, in New Zealand; 3, is a typical road and team waggon in Australia; and 4, is a quaint tonneau load of Australian children aborigines.

MR. C. J. GLIDDEN is again in London. The Ulysses of the motor car "cannot rest from travel," and he is going round the world once more to see "the cities of many men," countries and kingdoms. Without being exactly tired of Europe, he is this time at any rate going to make a start in Asia, having been favourably impressed from the accounts he has read, and all that he can learn from conversation with those who have been there, of the splendour of the Indian roads. He will proceed straight with his trusty Napier from London to Bombay in the *Mooltan* on November 10th. The Napier car, which has accomplished 20,000 of the 25,100 miles which go to Mr. Glidden's present round-the-world record, is still to all intents and purposes intact. The engine is the same, the gear-box is the same, the transmission is the same, and all its parts are the same. All that has been done to it, with a view to the present tour, is a thorough re-upholstering, painting, and small adjustments.

From Bombay, Mr. Glidden, who will, as usual, be accompanied by Mrs. Glidden, intends to proceed as far north in India as the roads will carry him, and confidently reckons on reaching Rawal Pindi and Peshawur. Thence Mr. Glidden intends to circle round through Cawnpore to Calcutta, from which point he is not quite certain whether he will descend the Indian Peninsula through Madras and Pondicherry, and so

take ship to Ceylon, or whether he will proceed by the roads of Burma, which, he is informed, are now admirable, through Mandalay to Rangoon, from there through Siam and the Malay States to Singapore, and then possibly back to Ceylon. Afterwards he intends motoring through the Philippines, a part of China and Japan.

Mr. Glidden is an enthusiastic devotee of the automobile as a means of travel. No method of travel is, in his opinion, so enjoyable, as it enables the traveller to see the country as he passes through it with an accuracy of detail of which railway travellers have no conception. How true this is, our readers will remember from the many splendid views of out-of-the-way parts of the world which Mr. Glidden has been good enough to send us from time to time during his past travels and which we have reproduced in the pages of the Journal. We give a few more of these now, obtained by Mr. Glidden on his last tour, as they most admirably illustrate the intimate contact into which the automobile brings the traveller both with the country and the people that lie along his route.

Mr. Glidden is busy mapping out the details of his course, and has an elaborate mass of correspondence from all the principal towns and districts he intends to travel through. He calculates that he will cover some

5,000 miles in India and from 1,000 to 2,000 miles in Ceylon, making altogether a tour of some 8,000 miles, which, when completed, will bring his touring record up to the extraordinary total of 33,000 miles. In out-of-the-way districts Mr. Glidden has had many quaint experiences with the language difficulty, but now he invariably, where necessary, takes with him an interpreter,

and the arrangements for relays of these necessary functionaries in out-of-the-way places is no small part of the successful "advance" management of the tour. We wish Mr. Glidden the best of good fortune and enjoyment on his long journey, and trust that he may still further popularise the automobile, and introduce it into districts where it has hitherto, at any rate, seldom been seen.

"JUSTICES' JUSTICE" AND "HEDGEHOG" ITEMS.

The "Handover" Colonel on His Defence.—We conclude that some of the remarks that his proceedings have evoked have ultimately penetrated the hide of that pachydermatous dispenser of "justice" who usually presides over the "legalised brigandage" of a certain notorious Bench. He has now publicly stated that he has invariably found the police to give their evidence in a "straightforward manner." We do not think that has ever been disputed. Police evidence comes out invariably with the straightforwardness of an oft-repeated lesson. He further added, in a particular case, that no notice could be taken of what the defendant's solicitor maintained, without admitting that the police had committed wilful perjury. Recoiling from such a dreadful suggestion, the magistrates of course found the unfortunate defendant guilty. But why it should be more unlikely for policemen, with every interest at stake, to commit this heinous offence, than for the innumerable defendants, usually men of good position and antecedents, is to some extent a mystery. The assumption, however, enables the "Handover" Bench to rake in fines *ad libitum*, and without compunction.

SUPERINTENDENT BOWLES of the local police thanked the Chairman of the Bench for the profound remarks referred to above, and added that as the police had received no complaints recently they had not been on motor (trapping) duty around Andover lately. The word in brackets is added by ourselves and we may also add that this confession of the Superintendent must undoubtedly be regarded as a testimonial to the efficacious manner in which the Automobile Association, since they have turned their attention to the Andover district, have been successful in restraining motorists from innocently exceeding the speed limit. Superintendent Bowles further added that the police would now be put back to their ordinary duties. A notable exodus of burglars and other cracksmen has accordingly taken place from the district, and "jemmies" can now be purchased in and near Andover at a moderate price. And so there is "peace" at Andover.

WE hope that similar satisfactory reports will soon be furnished by other superintendents of police in the districts where it has been the custom to concentrate the whole available police force on the roads, and to denude the country generally of police protection, for the sole purpose of extracting fines from automobilists.

THE general result will, we trust, be to accord a favourable response to the prayer of a gentleman living at Oatlands Park, near Weybridge—Mr. F. M. Frames—who has written to the Chief Constable of Surrey pointing out that in his district burglaries are now

being committed with practical impunity, owing to the whole available police force of the county being concentrated on and exhausted by attention to motor car traps. It is quite obvious that a policeman who has been for the whole day ensconced, we will not say in the classic pigstye, but in one of the umbrageous retreats on the Ripley Road to which we refer elsewhere, is hardly likely to be very alert during the night watches.

A SIMILAR wail comes to us from Cobham, a resident of that townlet, Mr. F. P. Armstrong, having remarked with much trepidation that the meagre police force of Cobham, Esher, and Ripley, regularly every day desert the villages which they are supposed to protect, and march out to deserted portions of the main Portsmouth Road, where they spend hours, and even days, in trapping or attempting to trap motorists. Mr. Armstrong of Cobham very naturally enquires, "What is the good of paying a police rate which is not decreased in any degree by the fines levied on motorists, while at the same time in the Walton and Cobham district burglaries have become regular 'fixtures'?"

Prejudice Against Motors.—In the Divisional Court, on Monday, before the Lord Chief Justice, Mr. Justice Wills, and Mr. Justice Darling, Mr. Huntley Jenkins (instructed by Mr. Staplee Firth) moved, on behalf of Sidney Owen Heywood, of Wickham Market, Suffolk, for a *rule nisi* for a writ of *certiorari* to issue, calling upon the Justices of the Borough of Bedford to show cause why a conviction by such Justices, made on or about the 11th July last, convicting Mr. Heywood of driving a motor car at a speed dangerous to the public on the Embankment there, should not be quashed, on the ground of bias and prejudice against motor cars, it being alleged that the Mayor of Bedford, H. BurrIDGE, Esq., had witnessed the alleged occurrence, had given the information which led to the proceedings against Mr. Heywood, had sat on the Bench when the case was tried, and had also retired with the Justices, but had come into Court before them, and stated that he would not take any part in the voting or decision of the Bench. The Court granted the rule asked for.

More Highwayism.—A Mr. J. H. Jackson was recently riding a motor cycle along the extremely indifferent road that stretches between Bishop's Stortford and Harlow. Owing to the condition of the surface of the road, he was going along at a leisurely 9 miles an hour or so, and police traps were accordingly far from his mind, conscious of its own rectitude. This, however, saved him not, for unwittingly he traversed one of these arrangements, and as he approached the end of it, without the slightest warning two policemen suddenly

jumped from a bushy hedge a yard or two in front of his nose, and shouted in loud tones to him to "stop." Doubtless, Mr. Jackson's nerves were upset by this sudden attack, and he may perhaps have concluded that he had dropped from the twentieth century back to the eighteenth, for this was the sort of summons that a lonely traveller was then accustomed to hear on Hounslow Heath or Shooter's Hill. Whatever the cause, he clapped on his brakes with such force that himself and his bicycle turned a complete somersault, the bicycle coming over as they sometimes do, and hitting him while he lay prone beneath it. When he had picked himself up in a seriously damaged condition, his left arm being badly injured, and his motor cycle a wreck, he was informed by the police, who made not the slightest effort to assist him in getting upon his legs again, that they had stopped him for the purpose of inspecting his licence. Mr. Jackson, whose arm, it is said, will be useless for a month, has been subsequently informed by the Chief Constable of Hertfordshire that the officers had a perfect right to stop him, though he expressed regret at the accident. Well, on this point, we beg to differ from the Chief Constable. A policeman has not a right to stop a motorist who is proceeding along the road, unless an offence can be alleged against him, and we think Mr. Jackson, who, by the by, is a clerk at the West Ham Police Court, would have a very good ground of action against the police, as their unwarranted interference, and particularly the manner in which it was effected, resulted in a serious accident.

But what a scandal the whole thing is! The inner meaning of the situation is so obvious. Here are policemen infuriated by a motor cyclist proceeding through their trap at a mere nine miles an hour, and making an excuse of a desire to see his licence, they jump out upon him so as to cause him serious injury. If the British public will continue to stand this sort of thing, it will stand anything.

Vindictive Persecution.—We referred last week to the tyrannical action of the Steyning Bench of Magistrates, in issuing a warrant for the arrest of Mr. John T. Day, who failed to answer a summons before them some short time back. It appears that the case is even more arbitrary and unconscionably tyrannical than we had supposed. Naturally, under the circumstances, we assumed, though we did not state, that the defendant had

neither put in an appearance nor been represented before the Bench in any way. But on the contrary, it now appears that he had instructed his solicitor to write to the Bench pleading guilty to the offence, and excusing his client's non-attendance. Under such circumstances, Benches of magistrates have been almost invariably willing to convict, and impose a moderate fine in the absence of the alleged delinquent, and this unusual action of the Steyning Dogberrys in this respect can be only attributed to pure spite due to a previous successful appeal from their decisions to Quarter Sessions, as we suggested last week. We are not at all certain as to whether, in the case of a defendant pleading guilty by letter, magistrates have the power to take this action, but whether they have or whether they have not, their doing so is a petty and tyrannical abuse of the powers with which a Constitution, accustomed to the reasonable exercise of functions on the part of its servants, has entrusted them.

Illegal Decisions.—A case of somewhat unusual interest was brought before the Hampshire Quarter Sessions, at Winchester, last week. Mr. Henry Welch-Thornton, of Beau Peare, Basingstoke, himself a magistrate, appealed against a conviction by the Andover Bench for having driven at "a speed dangerous to the public, &c.," on July 24th last. This was one of the cases from the notorious police trap near Hurstbourne Priors, in regard to which Lord Portsmouth erected the notice to which we referred at the time. It is satisfactory to learn that the appeal of the magistrate against the unwarranted decision of his brother magistrates was successful, and that the Court held there was no proof of danger to the public, having regard to the circumstances of the case.

THE King's Bench Division for Ireland last week (Lord Chief Justice, Mr. Justice Madden, and Mr. Justice Wright) granted to Mr. Samuel T. Robinson a conditional order quashing a Bray Petty Sessions decision under which (for not stopping his motor) the applicant was fined £3, with the option of two months' imprisonment, and the conviction endorsed. The grounds of the application were, (1) that there had been no offence committed under any act or bye-law; and (2) that there was no authority under the Motor Car Act to imprison for a first offence.

Speed Indicators and Motor Cars.—Following up the remarks that have already been made in our columns concerning the great utility of a speed indicator on a car, and the difficulty of correctly estimating speed without one, we are now able to give one or two further interesting points on the subject from some private tests which we have been making. Speaking from our own experience, which we find corresponds with that of several other users, the difference between "apparent" speed and "actual" speed is very marked, both when the car is travelling very slowly, and when it is running very fast. Below about 15 m.p.h. one is apt to make far too low an estimate, and conversely above about 25 m.p.h. the tendency is reversed. Frequently we have found the pointer indicating 10 or 12 m.p.h., when the occupants of the car would have guessed the speed to be 5 or 6 m.p.h., and more often than not, even those who have proved to be good judges at from 16 to 24 m.p.h. will, when it is only 26 m.p.h., put the speed

at 30 m.p.h., and then at 35 m.p.h. when the actual speed is only very slightly higher. Needless to say, even slower or faster speeds are even more deceptive, while the impression of speed varies considerably with different types of vehicle, and with the width of the roadway between the hedges. Another matter on which the result of practical experience may be found useful relates to the driving mechanism employed by some makers for their speed indicators. We refer to the use of a friction drive—with rubber-faced wheel pressed up against a flat metal disc on the road wheel—which does not at first appeal to one as being likely to prove sufficiently accurate for the purpose. Such a device, however, which obviously has the merit of being simple, is employed on the "Smith" instrument that we have—amongst others—been using, and we have been agreeably surprised, when carefully checking the readings, to find how remarkably correct they have invariably been in practice.

VANDERBILT CUP RACE.—A view of the crowd at the Grand Stand after the race. The scoring board is seen erected on the top of the stand, where some venturesome photographers and others have taken up their pitch.

RACES, RECORDS, AND TRIALS.

French Events in 1906.—As a result of the further deliberations of the A.C.F. Committees, the following supplementary decisions have been arrived at, in connection with the proposed touring events for next year. That the engine-power is to be calculated from the *piston area*, and that amongst the already specified classes of vehicles, there is to be an additional class for six-seated double phaetons without hoods.

Herkomer Cup.—Very active discussions are at present proceeding on the Continent in regard to the route for 1906 for the Herkomer Cup, June 10th to 20th. Several long "circuits" have been suggested, there being a considerable division of opinion as to whether the start should be from Frankfort or Munich. An influential following is in favour of Frankfort, but as the final decision rests with Professor Herkomer, it is thought that in all probability he will favour retaining Munich as the headquarters for this event.

Voiturette Competition.—The rules issued by *L'Auto* for this competition, taking place in Paris from November 21st to 27th, and summarised by us last week, have been approved practically in their entirety by the A.C. de France. The club made one or two suggestions and alterations, of which the only one of importance is that the minimum weight is brought down to 250 kilogs. instead of 350. Slight alterations are made in the allotment of

points, and passengers must be seated *side by side*. The selected course will be six times from Paris to Gaillon and back.

A HIGHLY amusing competition took place on the 26th of October on the big lake in the Bois de Boulogne. It was a motor boat fixture for the Branger Cup offered by the well-known Paris photographer, M. Branger, for the juveniles of Lutetia, and was to be competed for by toy motor boats, which, considering that they were not provided with the services of a pilot, gave a very creditable account of themselves. There was quite a concourse of people on the banks on either side, and at the crack of a pistol, off went the motor boats, driven by steam, electricity, petrol and spirit of wine. The course most of them took, however, was extremely erratic, and only one of them could be induced to directly approach the winning post, this, as it proved, being the slowest boat of all; but though slow she was steady, and kept her prow well fixed on the goal, with the result that she won the prize, while her faster competitors careered round the lake and ran into the bank in various directions. One tremendously fast little petrol boat came to grief, for it got so much way on that its bow plunged beneath the waves, there was a crack and a splutter, and the boat ultimately turned turtle. In fact, her performance was quite reminiscent of the Algiers-Toulon Race. The cup was ultimately gained by the steam boat Quinquina—the slow and sure competitor referred to above.

VANDERBILT CUP RACE.—An interesting diagram prepared by "The Automobile" is given above, showing positions of the contestants at the end of each round according to the actual time occupied by them. No. 17 did not start and is therefore omitted. The lines in this diagram have relation only to time and have nothing to do with numerical starting position or order of passage. All contestants are assumed to start together; therefore, as they can have no relative positions until the first round is completed, the names of the contestants are arranged in the order of their positions by elapsed time at the end of the first round. It will be noted that Warden and Sartori appear together in one space. This is due to the fact that both ran the first lap in the same time and were tied. The same applies to Keene and Hemery at the end of the second round. Campbell made only one round, at the end of which he was in twelfth place, and consequently is not represented by a line.

Ladies' A.C.—Among the hundred and fifty who attended the Hon. Charles S. Rolls' lecture — "Historical Reminiscences and Roadside Experiences"—at the L.A.C. on Thursday, October 26th, were the following:—Lady Cecil Scott Montagu, the first vice-president of the club, who welcomed Mr. Rolls and introduced him to the members; Lady Edward Spencer Churchill, the third vice-president of the club, who, after the lecture, thanked Mr. Rolls on behalf of the club; Mrs. Ainslie, the Baron and Baroness Campbell von Laurentz, Miss Christabel Browne, Captain Chichester, Mrs. Guy Hardy, Mrs. F. Morris Hartung, Mrs. Ashton-Jonson, Miss Kenealy, Mrs. Kellgren, Mrs. Mark Mayhew, Lady Manson, Mr. Lafone, the Lady Maud Parry, Mrs. Carpenter-Rowe, and the Hon. Lady Shelley. Within the last few months the following ladies have been elected members of the club:—Miss Ashwell, Lady Boughiey, Mrs. Henry Charrington, Mrs. Auerbach, Mrs. Akroyd, Mrs. William Chaver, the Dowager Lady Dudley, Lady Juliet Duff, Mrs. Louis Fagan, Mrs. Donaldson Hudson, Mrs. E. de Lisle, the Princesse de Polignac, Mrs. Harcourt Powell, Mrs. Douglas Murray, Lady Lathom, Lady Maud Parry, Mrs. Gordon Theed, Miss Stuart Wallace, and Lady Stirling.

VANDERBILT CUP RACE.—Lancia on the 120-h.p. Fiat, finishing fourth in the race. Lancia, it will be remembered, from our report of the race, in our issue of October 21st, made a splendid series of circuits surpassing everybody else's times, and his skillful driving for Italy, on the 120-h.p. Fiat, would undoubtedly have secured him the race, had it not been for the unfortunate collision which took place, when Christie ran into him on the course.

THE annual dinner of the Automobile Club will take place at the Hotel Cecil on Friday, November 24th, at 8 p.m.

THE Queen Mother of Italy has for a long time been, as all our readers are aware, an enthusiastic automobilist, but her record during the last month or so is certainly remarkable. From September 7th till October 17th she has, on a 24-h.p. Fiat car, actually covered some 4,812 kiloms. in spite of the bad weather frequently prevailing. Her daily average has been 80 kiloms. before lunch, and 120 kiloms. after lunch. She has traversed Switzerland, Germany, Holland and France, and on one occasion in Holland covered 283 kiloms. in a single day. Queen Margherita has received excellent consideration from the Dutch authorities, who appointed a special automobile, manned by three gendarmes, to precede her car and see that she was not subjected to any of the "attentions" which made some of her journeys in Italy far from agreeable experiences. Near Evian les Bains, a part through which the Queen passed, it appears that the peasantry are accustomed to play bowls on the high road, a custom which the advent of the automobile is likely to somewhat interfere with, and being irritated by the interruption occasioned, they endeavoured to barricade the road with a large beam put across it. Nothing would induce the bowl-playing peasants to remove the obstacle. A gendarme was summoned, and the peasants maintained that the car was exceeding the legal limit. Queen Margherita was unable to proceed till she had paid her persecutors a sum of 25 francs. We trust the authorities responsible for Evian les Bains will set their faces in future as much against playing bowls on the high road as the police for some time past have done against the time-honoured custom of football in the streets of Dorking and elsewhere.

Mr. H. Austin, who has for so many years been associated with the Wolseley Tool and Motor Car Company, Limited, and who is starting new works, where he will manufacture "Austin" Cars, at Longbridge, near Birmingham.

MR. H. AUSTIN, who has been so long associated with the Wolseley Tool and Motor Car Co., of Adderley Park, Birmingham, advises us that he is leaving the Company, and is starting works on his own account situated at Longbridge, near Birmingham, where he will manufacture vehicles which are to be known as the "Austin" cars. At first, Mr. Austin will turn out two sizes of tourist cars, viz., a 15-20-h.p. and a 25-30-h.p., both of which models will embody the best approved principles in design, and Mr. Austin proposes to use only the highest grade of materials in their manufacture. Moderation is to govern the selling price, and Mr. Austin hopes to make the car of his name a household word for reliability and good service. Captain Frank Kayser is associated with Mr. Austin in the new undertaking, and he will be assisted by a specially-selected staff, several of whom have been connected with him in the past. The works are of considerable extent, covering several acres, and are thoroughly suitable for the construction of automobiles of all types. Mr. Austin hopes to have his first 25-30-h.p. car on the road by the 1st of December, and to commence deliveries by the end of March, 1906. Mr. Austin sends us, in a tabulated form, an extremely interesting record gained by the cars which have been turned out by the Wolseley Company during his direction of that Company. This list bristles with gold and silver medals in all the leading reliability and consumption trials, exhibitions, &c., whilst in the speed events and hill-climbing contests, the number of winners makes a formidable show, these triumphs being in addition to the selection by the A.C.G.B.I. of the Wolseley racers in 1904 and 1905 for the Gordon-Bennett Race.

With the object of facilitating periodic cleaning, the "National" Exhaust-Silencer, of which we reproduce two photographs above, is constructed with but one central bolt to hold the various parts together. The interior portion—of which a separate view is given in the lower view—divides the box into four independent compartments, into which the gases are consecutively led by the perforated pipes that pass through, and carry, the three interior partitions. The exhaust-gases enter on the right, issue through the perforations into the first compartment, find their way into the central tube that leads them into the second compartment, have two perforated tubes available for conducting them into the third compartment, and finally arrive in the end compartment (which is open to the atmosphere) through the central tube once more. The lead-in tube and the central tube are, of course, plugged-up internally between the first and second and the second and third compartments, respectively.

VANDERBILT CUP RACE.—When tested before the American Eliminating Trials, and upon other occasions, the White Steam Racing Car—familiarily termed the “chicken-coop” by the Long Islanders—proved particularly fast, and therefore the poor performance of this vehicle in the race itself, caused considerable disappointment amongst its many supporters. Walter White, who drove the car had, however, a bad run of ill-luck. During the Eliminating Trials, in addition to serious tyre troubles, his pilot light was continually put out by a leakage from the water-tank, and it was, we understand, mainly owing to the trivial character of this cause of delay that the organisers of the race selected the White Steam Car to take part in the race itself. In the actual race, ill-luck with tyres more than ever seemed to dog Walter White's track, until it became almost hopeless for him to continue running, and when, with practically no chance, he was striving to make up for lost time, he blew a gasket joint in the cylinder head, and failing, in spite of every effort, to obtain a new gasket, he perforce had to throw up the sponge. In our photograph above, which was taken on the first run, it will be noticed that the car is travelling on three tyres only.

THE quaint old custom of holding an inquest by the City Coroner in cases of fires within the City boundaries, was celebrated on Friday last, when the fire which took place in Cornhill on the 16th instant, due to the lorry laden with petrol cans belonging to the Anglo-American Oil Company bursting into a blaze, was inquired into. From the “inquest” it transpires that there were 700 empty cans and 100 full ones on the lorry. There was a general agreement among the witnesses that there must have been a leaky can in the load, and that the leaking petrol was presumably set fire to by the rear lamp of the vehicle. This is the view taken by the jury, who accordingly returned the following verdict:—

“The jury are of opinion that the fire was caused by spirit leaking from a can and coming into contact with an improper lamp. They consider the carriage of petroleum through the streets should be regulated by the Petroleum Acts.”

It is very disconcerting to learn that the Marylebone Council has been recommended by its General Purposes Committee to support the London County Council's projected electric tramway from Marble Arch along Edgware Road to Cricklewood, *on condition that the Borough was not required to contribute to any necessary street widening.* For a long time past the way in which the affairs of Marylebone have been managed (?) has even caused judges in the High Court to describe them as providing “a complete satire on municipal trading.” Should the Council agree to this proposal, it will keep up the tradition of the satire. To think that an important local body can be so short-sighted in an important matter of this kind as only to consider whether the Borough will, or will not, be put to an immediate expense, is more than ridiculous, it is a scandal.

VANDERBILT CUP RACE.—The White Car on the second and third circuits, still struggling against tyre troubles. In the left picture, a front tyre is being replaced, and on the right a rear tyre is receiving attention.

Our photograph represents Mr. C. B. Gregson taking his 15-h.p. Spyker Car up Steep Hill, Lincoln. The gradient of this incline is, we learn, 1 in 4 $\frac{1}{2}$, and it must in this respect rank among the most severe "test hills" in England.

MOTOR BOATING.

THE French Maritime Week has been fixed for next year to take place at Havre from July 11th to 16th, a number of motor boat events being included in the programme.

CANNES annual regatta has been fixed for March 23rd to April 8th, between which dates the Alexander Burton Cup for motor boats will be run off.

THE Coupe Dubonnet for motor boats is to be disputed on July 8th next at Mantes.

Les Sports announce that they have selected July 10th and 11th for their motor boat race on the lower part of the Seine to the sea.

"PARIS-TO-THE-SEA" race for motor boats is to commence on July 8th next year, the first stage being to Mantes.

Motor Boat Run from Southampton to the Thames.—A very venture some engine-non-stop motor boat run was carried out last week under trying circumstances by Mr. E. Higley Halliday, of the firm of Messrs. Dixon and Halliday, motor boat builders. Mr. Halliday started from Southampton at noon on Wednesday in last week, and being determined to demonstrate that if he got to his goal he would do so without re-starting the engine, he handed over the starting handle to a third party as soon as he got under weigh. There was no means by which Mr. Halliday could have re-started his engine had it actually stopped, and had it done so the 30-foot motor launch Iris, on which he was making the attempt, would have become derelict in the Channel, and would have incurred a very excellent chance of being run down by some passing steamer during the night. The love of excitement strong within him, however, induced Mr. Halli-

day to take the chance, and he succeeded in getting well up the Thames to practically alongside Gravesend when his petrol supply gave out. He had exciting adventures. Everything went well till he ran into a fog, and then he was in trouble, for the petrol tins with which his boat was stored upset his compass needle, so he could not steer by that, and stars there were none. So he had to get along as best he could, dead slow, taking soundings at frequent intervals. On one occasion he nearly ran into a fishing boat which had its lights out. On another occasion he was overhauled somewhere near Beachy Head by a Channel pilot, who came almost alongside, and demanded to know "what sort of Robinson Crusoe business this was." Mr. Halliday, fortunately for himself, had plenty of provisions on board, particularly turtle soup, which he managed to heat with a Calorit apparatus. But what was his disgust when just preparing to swallow a bowl of it, nice and hot, to find that

he had to employ it instead to thaw his frozen-up carburettor! However, all's well that ends well, and Mr. Halliday safely arrived in the Thames where he was picked up by the motor yacht Kromhaut, near Gravesend, just when the engine had come to its last explosion from want of petrol. Of course, but for the unfavourable circumstances he encountered, and with clear weather, he would have been easily able to run the entire distance up to Chiswick, his intended goal, on the sixty gallons of petrol that he carried with him. The performance, however, from whatever point of view it may be regarded, is a remarkable testimonial to the possibilities of the motor boat, and to the pluck and endurance of Mr. Halliday. At the same time, one cannot help thinking that had he placed his starting handle in a sealed box, so that he could have got at it in real need, he would have been incurring less dangerous risk, and would have demonstrated the reliability both of the boat and its engines quite as effectively.

MOTOR CYCLING.

Passenger Motor Cycle Trials.—The awards in this contest which took place on Saturday, October 21st, under the auspices of the Auto Cycle Club, are as follows: Gold medals—9-h.p. Riley (No. 12), 4 $\frac{1}{2}$ -h.p. Phoenix (No. 9), 6-h.p. Leader (No. 7). Quadrant Carettes (Nos. 2 and 10) one medal between both. Silver medals—6-h.p. Singer (No. 6), 6-h.p. Singer (No. 15).

THE Mersey Railway Company, as we have already chronicled, will be in readiness within the next fortnight to run the service of motor 'buses from Birkenhead which they have been for some time organising. The first route to be opened is that from Palen Grove to Central Station, and four 'buses will be required for the route. Some hostility, or perhaps we had better say friendly rivalry, has been evinced by the Corporation, who intend at an early date running their own service of motor 'buses, but provided the competition is not carried on on too narrow lines, this ought to be to the general benefit of the inhabitants.

THE Brighton motor track was considerably damaged on Monday by the rough seas experienced.

THE magistrates at Bishop's Stortford are to be commended on their moderation. Evidently it is not their object to rake in fines in the manner of some other Benches we could mention. A Mr. Frederick Menzies, of Mayfair, was recently summoned to appear before them for exceeding the speed limit, but was unable to attend, and wrote to the Bench enclosing a £10 note to cover the fine. The magistrates extracted 50s., and returned Mr. Menzies the balance, doubtless to his no small surprise.

AT the auction sale of the Motor House, on Thursday of last week, several more well-known buyers participated, amongst the more prominent being the Duke of Manchester, who indulged, "under the hammer," in a 70-h.p. Panhard and a 30-h.p. 6-cylinder car. In addition, the auctioneer was successful in disposing of sixteen other 4-cylinder cars at high prices. The company's business appears to be growing very rapidly, and has necessitated their securing further new premises. We learn that they have now purchased the well-known premises of "Automobilia," at 532, Oxford Street, W. In addition to the premises, the company have also purchased the goodwill, stock of cars, accessories, plant, machinery, furniture, fixtures, and fittings, and the stock will be duly disposed of by them by public auction during the very special four days' sale they are holding on November 21st, 22nd, 23rd, and 24th. Extensive and elaborate alterations will be made on these Oxford Street premises, prior to their being subsequently opened for the general business of the Motor House.

A GOOD deal of fun has been made by some of the daily papers over the romantic hiding-places which the organisers and "magistrates' highwaymen" on the Ripley Road have arranged for themselves. Presumably they are tired of the pigstyes with which the police-trap has for so long been associated, and they have erected in consequence leafy retreats, overbranded with boughs of trees and other verdant accessories, in which they succeed in hiding themselves even more effectively from the gaze of approaching motorists than they have ever been previously able to do—in the ditches, sheds, and other fixtures which Nature or art has provided. Absolutely concealed from the public gaze in these umbrageous thickets, they pounce out with even greater effectiveness than before, or at least did so till the Automobile Association extended its activity to the Ripley Road. Since then the policemen, until the recent bad weather, have occupied the umbrageous thickets with comparative few excuses for emerging therefrom, and it is currently reported that they are now generally studying the first Eclogue of Virgil.

"THE Yorkshire Union of Agricultural Clubs" is not a name which conjures up ideas of extreme anxiety for progress, mechanical or otherwise, and it is therefore not at all surprising that at a meeting of this body the following resolution was proposed:—

That the maximum speed of motor cars be twelve miles an hour, and local highway authorities be invested with power to reduce the limit of speed when driving through towns and villages, and that the penalties be increased, and the owner or hirer, if present when the offence is committed, to be liable to the same punishment as the driver, and that the Yorkshire Union of Agricultural Clubs be represented before the Royal Commission.

Opinions were not altogether one way, however, and the chairman of the meeting, Major Dent, was opposed to a speed-limit, and maintained that the real test was danger to the public. As soon as, in his opinion, motors became generally driven by gentlemen, "we shall very soon get them to observe all the decencies of the road." Finally Major Dent's amendment was carried by the bare majority of one vote. The significance of Major Dent's remarks is greatly increased when we bear in mind that he is a member of the notorious Knaresborough Bench.

Parsons' Non-Skid Owner Wanted.—Mr. C. J. Allin, Hon. Secretary of the Derby Automobile Club, writes us as follows:—"A Parsons' non-skid has been found near Belper this week. In case this should belong to any of your numerous readers, would you be kind enough to mention this fact in your next issue, and state that if they will apply to me (St. Albans, Friar Gate, Derby), stating size and where lost, I shall be pleased to give them the address of the finder."

The Motor Omnibus Boom.—To give an idea of the demand there is for petrol motor omnibuses, the Motor Car Emporium write us that last week they made their record booking of orders in one week—108 for the London General Omnibus Company, 16 for Italy, 5 for Ireland, 12 for Egypt, and 25 for a new London company. They also secured orders from the Glasgow and South-Western Railway, and other railway companies.

The first of the Motor Cabs which the London Motor Transit Company have acquired for placing in regular service on the streets in the Metropolis. They intend to introduce 100 cabs within the next few months. Each cab is to be lighted electrically, and warmed internally by the water that cools the engine.

SIR ALBERT K. ROLLIT, M.P., will open the forthcoming Stanley Show on Friday, November 17th.

THE firm of Fils de Peugeot Frères have decided to construct a large number of standard voiturettes for 1906, the first turnout to be 1,000 cars.

DR. H. R. MILL has brought out a book which he entitles "The Siege of the South Pole." He is very sanguine of the capabilities of the automobile, and thinks that Captain Scott would have done much better than he has done if, instead of using dogs and men to draw his sledges, he had proceeded to storm the South Pole with motor cars. He observes :—

If a motor car ran at the rate of only 5 miles an hour for a couple of days before it broke down, it would give a sledge party a *dépot* far from their main base, and allow of the inspection of a much greater area than could otherwise be examined.

THE Negus of Abyssinia (that is the official title of the Emperor Menelik) has always been recognised as a progressive Sovereign, and now he is importing traction engines, built by Messrs. Fowler and Co., into his Empire of Abyssinia. The engines, which are of the standard single-cylinder type, used for agricultural purposes, are now being conducted by representatives of the firm across trackless wastes on their way to Adis Abeba, where they are to be put to work.

INSTRUCTIONS in technical subjects by correspondence is a leading feature of popular education in the United States, and we are, therefore, interested to observe that the method has now been extended to automobile topics, and that a Correspondence School of Automobile Engineering has been established in Akron, Ohio. The syllabus appears to be an extensive one.

Considerable ingenuity is being almost daily brought to bear in the design of motor car bodies, whereby increased comfort and utility is embodied in up-to-date vehicles. Miss Beatrice Savile is responsible for certain innovations in the body-work of the above 24-h.p. De Dietrich Car. Some of the more special features which Miss Savile has introduced are the side glass panels which can be taken out at a moment's notice, and the car converted into either an open limousine or a covered brougham, thus rendering the car suitable for either town or country work by day or night, summer or winter. The door-window slides behind the side window panel and does not interfere with the view when touring. Good seating accommodation is provided on the rear seat facing forward, and an extra drop seat or hinged table or parcel rack can be fixed opposite. The double curve in the design of the carriage body itself gives a particularly pleasing effect to the general appearance of this very beautiful carriage.

THE Local Government Board have consented to issue an order fixing the speed of motor cars, in response to an application by the Kingston-on-Thames Corporation for a six-mile limit, to ten miles an hour in ten of the principal streets of the town.

It is satisfactory to learn, in reference to a recent midnight meeting of the members of the "London 'Bus, Tram, and Motor Workers' Union," that the horse 'bus drivers of the metropolis are universally coming to recognise that the motor 'bus is the 'bus of the future, for we are informed that most of them are taking lessons in learning how to drive motor 'buses in their spare time, although how much spare time the average horse 'bus driver enjoys is usually what mathematicians call an infinitesimal.

WE learn that Mr. George Cecil, who has been a profuse contributor of chatty and interesting motoring articles to the Press, is about to take over the editorship of the *Boudoir*, an excellently got up and well-illustrated periodical, which has shown its enlightenment by making its readers familiar with the advantages of motoring as a sport and pastime.

New Cars for Old.—The Gladiator Company notify us of a novel departure on their part in connection with their 2-cylinder Gladiator cars. Any owner of one of these is invited to give particulars of the performance of the car since it entered their possession. Then the owner who proves that his car has given the most satisfactory results will have, absolutely gratis, a new 1906 2-cylinder 10-h.p. Gladiator in exchange for his old car.

CLUBS AND ASSOCIATIONS.

British Empire Motor Trades Alliance.—This Association has been registered as a limited liability company under the Companies Acts, 1862 to 1900. (Company limited by guarantee, and not having a capital divided into shares). The members consist of the following firms:—Albany Manufacturing Co., Ltd.; Argyll Motors, Ltd.; Ariel Motor Co., Ltd.; Sir W. C. Armstrong, Whitworth, and Co., Ltd.; Brampton Bros., Ltd.; Clarkson, Ltd.; R. W. Coan; Daimler Motor Co., Ltd.; Dean and Burden Bros., Ltd.; Dunlop Pneumatic Tyre Co., Ltd.; S. F. Edge, Ltd.; Electric Ignition Co., Ltd.; W. T. Flather, Ltd.; Gratzel Patents and Engineering Synd., Ltd.; Hoffman, Manufacturing Co., Ltd.; Humber, Ltd.; Iden Motor Car Co., Ltd.; James and Browne, Ltd.; Lacre Motor Car Co., Ltd.; Legros and Knowles, Ltd.; Joseph Lucas, Ltd.; Maudslay Motor Car Co., Ltd.; New Arrol-Johnston Car Co., Ltd.; Palmer Tyre, Ltd.; Phoenix Motor Co.; Price's Patent Candle Co., Ltd.; Simms Manufacturing Co., Ltd.; Star Engineering Co.; Sunbeam Motor Car Co., Ltd.; Swift Motor Co., Ltd.; J. I. Thornycroft and Co., Ltd.; Wolseley Motor Co., Ltd.; Worsnop and Co., Ltd.

Motor Union Annual Dinner.—The annual dinner of the Motor Union has been arranged for Wednesday, November 22nd, at the Trocadero Restaurant. For the convenience of provincial members of the Union, it has been fixed for the week of the Olympia Show. As the application for tickets will be very large, members of the Union who desire to be present should secure their seats without delay. The chair will be taken by the Hon. Arthur Stanley, M.P., and some distinguished guests will be present.

Motor Yacht Club.—At the last meeting of the Committee it was unanimously decided to open a subscription list to present the Societe de la Voile d'Arcachon, purely a sailing club, with a Cup to be raced for next season, as a small token of the unbounded hospitality which they recently extended to the members of the British Team for the International Cup.

Nottingham A.C.—Professor Robinson, Principal of the Engineering Department of the University College, delivered, on October 23rd, an interesting lecture, before the above club, on "Motor Car Engines." In the course of his remarks, Professor Robinson dealt in a lucid manner with the causes of pre-ignition and gave many interesting points about ignition systems generally. The lecture was rendered particularly interesting by the various models which the author collected for the purpose of illustrating his remarks.

THE Annual Invitation Smoking Concert given by the Stanley Cycling Club, just previous to the holding of the Show, will again be held this year at the Queen's Hall, Langham Place, on Friday, November 3rd. Tickets can be obtained from the hon. sec., Mr. E. P. Hewkin, 106, Tollington Park, N.

COMMERCIAL POINTS.

The Krebs Carburettor.—Arrangements have now been made, at the Panhard and Levassor repair works in London, for supplying and fitting this well-known automatic carburettor to any existing cars, at a greatly reduced price.

THE Earl of Mexborough has placed an order for one of the new 22-28-h.p. 1906 Crossley cars.

WE learn from the Simms Manufacturing Company that the engine fitted to the motor road-roller, illustrated in last week's issue, is made by them, and is one of a number supplied to Messrs. Barford and Perkins, who constructed the machine.

MESSRS. FRANK LITTLE AND CO., of Newcastle-on-Tyne, are pushing the motor business considerably in their district, both for business and pleasure vehicles. At the recent Grocers' and Allied Trades Exhibition at Newcastle they got together an excellent exhibit, the feature being commercial motor cars suitable for these particular trades.

At their stand at Olympia during the Motor Show, the Gladiator Company advise us that they will have a useful little novelty for distribution, one of which will be presented to any applicant. It is a small instrument named the Metrometre, and its purpose is to enable motorists to ascertain the horse-power of an engine. Those not visiting the Show can have one of the instruments by forwarding three stamps to the Gladiator Company, 8 and 9, Long Acre, London, W.C.

MESSRS. HUMBER, LIMITED, have decided upon issuing, for the future, a guarantee for twelve months from the date of purchase with all of the motor cars of their make, relying with absolute confidence on the British workmanship and high-class material which they embody in their motor vehicles. The Humber Company are not only now placing their cars advantageously in the home market, but have built up an important export business which necessitates the dispatch of cars every week to widely-separated parts of the earth, many of the Company's make of car finding their way to France itself.

THE Crossley-Leyland motor 'bus, which was illustrated in our last issue, is, we learn, fitted with Royal Sirdar Buffer tyres.

A GOLD medal has been awarded at the Liege Exhibition to the Halle Spring Wheel, a set of which were recently subjected to a 4,000 miles test under the auspices of the Automobile Club.

LEGAL CASES.

Lights: New Decision.—A new point was raised at West London Police Court on Tuesday, when Mr. Walters, solicitor, of Royal Crescent, Kensington, was summoned for neglecting to have his motor car lamps lighted at night. Defendant contended that as the car had been brought round to his house door to await him for use after dinner the car was not actually in use. Mr. Lane said the point was a new one, but he must conclude that any car standing in a public place at night, whether in use or not, must be lighted. He imposed a 10s. fine.

CORRESPONDENCE.

* * *The name and address of the writer (not necessarily for publication) MUST in all cases accompany letters intended for insertion, or containing queries.*

SAVE US FROM OUR FRIENDS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Surely the promotion of any huge scheme for providing motor main roads is most urgently undesirable at the present critical moment, just when all moderate motorists are trying their very utmost to show the public that cars are so controllable as to be absolutely safe on ordinary highways or even country lanes.

Cannot point-to-point speedists defer these somewhat visionary plans until a later stage of development, instead of raising up, so inopportunistically, a host of fresh enemies from amongst railway shareholders, and, worse still, giving away ready-made "expert" arguments to the Highways Protection League?

Not in vain has their secretary advertised for help; but at least we did not expect to be so sorely wounded in the very house of our friends!

Your obedient servant,
OCTOBER 26TH.
LEVESON SCARTH.

"PETROL, STEAM, AND THE CLUB."

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Perhaps it might interest Mr. E. W. Sheppee to have me reply to his letter, which appeared under the heading of "Petrol, Steam, and the Club," on page 1334 of your issue of October 28th.

The reason I think my reply might interest him is that I sell more steam motor cars in Great Britain than all the rest of the steam car companies put together.

My reply to the accusations against the A.C.G.B.I. would be that in every instance the accusations are utterly unfounded and untrue.

I am, yours faithfully,
35-37, King Street,
Regent Street, October 26th.
FREDERIC COLEMAN.

Good News for Owners of De Dion-Bouton Cars.—Owing to the fact that De Dion-Bouton cars are different in design and construction to ordinary types, and the large number in use in this country, the company have opened workshops in London for the repair of their cars. This step has been further prompted by the difficulty frequently experienced in many districts in obtaining proper attention to repairs. Owners of De Dions will in the future be able to have their cars attended to by men specially trained in De Dion-Bouton car construction. A large stock of parts of all the company's models is held by them in London, consequently prompt attention can be given to all and sundry requirements. Enquiries should be addressed to the head office, 10, Great Marlborough Street, London, W.

ARGYLL MOTORS, LIMITED, have had an extremely successful year. The directors at their meeting on Monday in Glasgow recommended a dividend of 10 per cent. on the ordinary shares, and 6 per cent. on the preference. The profits amount to £32,531, of which the directors have written £5,897 to depreciation, £8,877 to vendors in terms of the prospectus, £3,000 to preference share reserve fund, £4,000 to general reserve, and carry forward £3,000.

THE net divisible profits of the Rover Cycle Company for the year ending August 31st last amount to £16,211, after providing for debenture interest, directors' fees, depreciation, bad and doubtful debts. Out of this the directors propose paying a ten per cent. dividend for the year, to place £5,500 to general reserve, and carry forward £3,920.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

2530. February 8th, 1905. Improvements relating to Driving Gear for Motor Cars and for other Services. Edgar J. de Normanville, 6, Clarendon Crescent, Leamington Spa, and Henry J. Lee, 41, Widdrington Road, Coventry. This invention relates to driving gear for motor cars, the object being to construct and arrange variable speed gear of the epicyclic type in compact form, and suitable for convenient combination with the differential gear. There are two figures. Fig. 1 is a central longitudinal sectional elevation. The complete epicyclic trains forming the speed gear and also the differential or balance gear are mounted about a one-part or undivided shaft or axle, *a*. Upon one end of a sleeve, *b*, formed with or fixed to a chain or other wheel or driving element, *c*, is a central gear-wheel or pinion, *d*, forming the sun-wheel of an epicyclic system. Three planetary wheels or pinions, *e*, arranged in constant gear with the sun-wheel, *d*, are mounted on a rotatable carrier comprising a brake-drum, *f*, which may be set free to rotate or held against rotation. With each of the

motion from the rotation of the planets on their respective axes, *i*, but will also receive an increased movement due to the rotation of the planet carrier set up by the arrest or retention of the toothed ring, *m*, engaging the primary planets, *e*. For the third speed, a second sun-wheel, *n*, is freely mounted on the shaft, *a*, and connected by a sleeve extension, *n'*, with a brake-wheel, *o*, whereby it may be prevented from rotation at will. The sun-wheel, *n*, gears with the extensions, *i*, of the secondary planets, *e*. When the sun-wheel is held by its brake-pulley, *o*, the other brake-pulleys of the complete device being free, the toothed ring, *j*, of the driven element, *k*, will receive motion from the planets, and also from the planet carrier, *f*. But the latter now receives its motion from the sun-wheel, *n*, instead of from the larger ring, *m*, as in the second-speed drive, with the result that an increased rate of carrier rotation is obtained, which, together with the rotation of the secondary planets on their own axes, gives the required speed to the driven element, *k*. For the fourth or high speed, it

planetary pinions, *e*, there is formed an extension or another pinion, *g*, which engages a secondary or intermediate planet pinion, *h*, and an extension, *i*, from this latter pinion engages and drives an internally-toothed ring, *j*, attached to or forming part of the driven element, *k*, enclosing the differential gear. With a set of three of the planetary pinions, *e*, with their extensions, *g*, there is a set of three of the intermediate or secondary planets, *h*, each having the extension, *i*. Both sets are mounted on the carrier, *f*, by means of the pins *l*, forming the axes of the respective duplex wheels or pinions. This mechanism, when the carrier, *f*, is held or prevented from rotation by a brake-strap or similar device, constitutes the first or slow-speed drive. The second-speed drive is obtained as follows:—Surrounding the primary planet pinions is an internally-toothed ring, *m*, the exterior of which serves as a brake-wheel or pulley. When the ring is held against rotation, and the planet carrier, *f*, is released or set free to rotate, the toothed ring, *j*, forming part of the element, *k*, to be driven, will receive

is merely necessary to clutch or lock together any two of the sets of intermediary gearing to give a direct connection between the driving and driven parts. To obtain a reverse drive, a supplemental pinion, *r*, is formed or provided with each of the primary planets, *e*, but of a smaller diameter. The pinions, *r*, gear with a loose sun-wheel, *s*, adapted to be arrested by a brake-pulley, *t*, as with the parts previously described, so that the planet carrier, *f*, is rotated in a direction opposite to that of the rotation of the main or driving sun-wheel, *d*, referred to—October 11th, 1905.

26753. December 8th, 1904. Improvements in or relating to Carburetors particularly applicable to Internal Combustion Engines. Edmund W. Lewis, 2, Albany Road, Coventry. In this invention the fuel is drawn from the nozzle, not directly by a vacuum, but by the velocity of the air passing the nozzle, and this velocity can be controlled by hand or otherwise, the controlling means being connected to the throttle-valve, so that as the throttle valve is opened to cause the suction on the nozzle to become

NEW COMPANIES REGISTERED.

[Taking powers to manufacture or deal in motors, motor cars, or accessories, either as their principal or part of their objects.]

Aster Engineering Company (Limited).—Capital, £50,000 in £1 shares. Object, to adopt two agreements with the Société l'Aster and Aster, Limited, respectively, and to carry on the business of manufacturers of motor cars, omnibuses, &c., makers of chassis, machinery, &c. First directors, M. Cheronet (chairman), A. Monard, L. C. Getti, G. M. Bertault, and S. D. Begbie.

Buckingham Gate Garage and Engineering Company (Limited).—Capital, £2,000 in £1 shares. Object, to acquire the lease and assets of the business carried on at Buckingham Gate Garage and Engineering Company.

Leader Motors (Limited).—Capital, £15,000 in £1 shares.

Lenox Autocar Company (Limited).—Capital, £5,000 in £1 shares. Object, to acquire the business of the Lenox Autocar Company, 81, Dalmain Road, Forest Hill, S.E. First directors, A. J. Kemp, A. H. Salmon (managing director), H. Pantin, and C. Foster.

PUBLICATIONS RECEIVED.

greater the path for the air near the nozzle is simultaneously enlarged so that the greater quantity of air necessary passes at the required velocity to enable it to take up just the proper amount of fuel desirable. There is one figure, a section. To effect the end above described, the top of the nozzle or fuel outlet, *A*, is arranged close to the wall, *B*, of the spray-chamber, and a cylindrical plug, *C*, is rotatably inserted in the spray-chamber between the nozzle and the engine. This plug, *C*, is conveniently larger than the bore of the spray-chamber, and has formed in it a transverse passage, *C'*, each end of which may communicate with the spraying-chamber on one side of the plug. By rotating the plug, the registration of these ends with their respective parts of the spraying-chamber may be varied so as to operate as a throttle-valve in the manner of a plug-cock. The side of the plug adjacent to the nozzle, owing to its proximity, operates to impart to the air passing the nozzle the required velocity, whilst the other side operates as a throttle-valve in substantially the usual manner. The plug may be arranged as close to the nozzle as possible, and the passage, *C'*, is arranged so that as the plug is rotated both ends are simultaneously closed and opened.—October 11th, 1905.

COVERS FOR BINDING VOLUMES.

Price 1s. 6d.; Post free, 1s. 9d. Can be obtained through the usual Agents, or direct from the Publishers.

Cheques and Post Office Orders should be made payable to F. KING AND CO., LIMITED, 44, St. Martin's Lane, W.C., and crossed London and County Bank; otherwise no responsibility will be accepted.

When any difficulty is experienced in procuring the Journal from local news-vendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance as above.

NOTICE.—Advertisement instructions should reach the office, 44, St. Martin's Lane, W.C., by first post, Wednesday. The latest time for receiving small alterations for Advertisements is 12 noon, Wednesday. No alterations can be made after that hour.

DIARY OF FORTHCOMING EVENTS.

PASSING EVENTS.

Evidences of Increasing Prosperity.

THIS year's balance-sheet of the Daimler Company, which has just been issued, will, in all probability, be looked upon in future as a very significant land-mark in the progress of the automobile industry in this country. The results of the year's trading are not merely satisfactory; it is not too much to say that they exceed our most sanguine expectations. On an issued capital of £62,269 (£1 ordinary shares), what amounts to a dividend of 10 per cent. has been declared, while on a nominal capital of £64,200 of preference shares, of which half only has been called up, a return equal to a dividend of 13½ per cent. has been arranged for, and while these thumping dividends will go into the pockets of the shareholders, no less a sum than £30,000 is being carried forward to the benefit of the reserve fund. When we call to mind the vicissitudes which all the pioneer motor companies passed through in the earlier days of the industry, the splendid success of the Daimler Company's past year's trading, which these figures bear witness to, is a proof of triumph in quite a number of different directions. It is a triumph for the business management, the technical staff and the Board of Directors, who have successfully pulled

the company out of a position which was far from roseate. It is a proof of the great and growing vitality of the British automobile movement, and the value of the British market, and it is above all an illustration of what manufacture on a proper scale, with sufficient capital behind it to enable up-to-date production to be carried out on the large standardised scale, which alone means adequate profit, can effect.

It is pleasing to find that the Daimler Company does not stand alone as an automobile manufacturing concern in which the past financial year has been characterised by a phenomenal success. The balance-sheet of Argyll Motors, Limited, to which we referred last week, is satisfactory reading for the company's shareholders, a dividend of 10 per cent. on ordinary shares and 6 per cent. on preference shares having been declared.

* * *

May they Not Encourage the Company Promoter.

THESE satisfactory figures and balance sheets are also evidence that the automobile movement may now be completely regarded as having recovered from the evil results of the sinister operations of company promoters, which almost wrecked it for so long in this country, and paralysed its prosperity for quite a number of years. It is earnestly to be hoped in the interests of the movement, that the satisfactory position of which these two great companies is such unmistakeable evidence, will not have the effect on any serious scale of causing unprincipled company promoters who have no real trading interests at stake to once more direct their malign influence upon the automobile movement. "Operators" of this sort would use automobilism to-day, meat extract to-morrow, and chemicals on the day after, if such tactics seemed to afford a chance for floating companies which would successfully transfer the money of the public to their own pockets, without caring in the slightest what ruin they might strew around them. Should they again devote themselves to the automobile, we feel convinced that the industry is now strong enough to prevent their operations producing any very dangerous results, but, nevertheless, a good deal of harm might be done. It is harm which the public can prevent by adopting a sensibly critical attitude to any such promotions which might be made, and by remembering that the high profits have been earned, and the splendid financial position to which we refer has been attained, solely by the persistent exercise of the ablest technical ability, the profoundest business capacity, and the most unrelenting and ceaseless application of tireless energy and ever-ready initiative.

* * *

Killing the Goose that Lays the Golden Eggs.

THE phenomenally reckless expenditure of the London County Council, which has for so long been a topic of animated discussion in almost any paper in the Metropolis from *The Times* to Mr. *Punch*, and which is due in the main to the Council's unwavering determination to electrotramify the greater part of the Metropolis, without pausing to consider the disadvantages of this already nearly superannuated means of locomotion, is having an effect which the Council, when it embarked on its wild-cat schemes of electrification, steamboat service, and other form of municipal trading, little contemplated. While the general ratepayer, the individual represented in *Punch* with a rotund figure decorated by a white waistcoat, appeared as the principal

victim, the community as a whole bore the situation with patience and fortitude, particularly those who were not ratepayers. The Council doubtless thought that prosperous tradesmen, merchants, and the like, were fixtures in the Metropolis, who, however the burden of rates ran up, though they might groan in public and use forcible and picturesque phraseology in the privacy of their homes, would have to "pay, pay, pay," and look pleasant or the other thing. The case of the great industries—the few of them that remain, we should say, still clinging to London—is apparently forgotten. Great manufacturing concerns are with very questionable wisdom most heavily rated, and the enormous rise in London rates accordingly means a tax upon them which may go a long way to annihilating the difference between working at a profit and working at a loss. As among the first fruits of the disastrous municipal expenditure, therefore, we must count the fact that Messrs. Yarrow and Co., of Poplar, contemplate transplanting their great works from the banks of the Thames to the banks either of the Tyne or the Clyde, and they are not, if all that we hear is to be believed, the only great firm that contemplate a similar exodus. Let us trust that the effect will be to warn the County Council in time. London has lost one after another among the great industries which supported its population in the past. To drive the remaining ones elsewhere by perpetually running up rates is simply killing the goose that lays the golden eggs. We hear enough of the distress of the east of London. It is shocking and serious enough in all conscience as it is, and Poplar would appear to be one of the most distressful districts. Its state, after the removal of the Yarrow works, will be simply calamitous. The removal of other works will affect other districts in a similar way; and though the gratitude of electrical contractors to the County Council is doubtless great, we do not hear of any proposals on the part of such firms to migrate to London in recognition of the manner in which the Council has supported them. The prospect of a London of the future, all of whose industries have been driven elsewhere by reckless County Council expenditure, is a prospect which ought to give even County Councillors themselves pause.

* * *

The New Rules for the Tourist Trophy.

ON another column of the present number of the Journal we reproduce the revised rules which the Races and Technical Committees of the Automobile Club have elaborated for regulating the Tourist Trophy Competition of next year, which may, by the way, be run in May instead of September. The underlying spirit of the regulations is, of course, identical with that which governed the rules this year, but we are glad to see that a number of highly important alterations and additional provisions have been introduced, and we are confident that they will undoubtedly have the effect of causing the competition to approach more completely to the excellent ideal which its original projectors and organisers set before themselves. It will be very difficult for the reader, at first sight, unless he has an unusually good memory, to fully grasp how the new rules differ from the former ones, but their more important aspects may be briefly summarised as follows:—Most important of all, possibly, is the reduced fuel allowance, the natural tendency of which will be to lower the average speed maintained throughout the race, but hardly less so is the abolition of the

"maximum" weight limit of the chassis. General satisfaction will be felt with the latter, for the 1,600-lb. limit, which we have protested against from the very first, was conclusively shown to be detrimental in the Isle of Man this year. It is intended, moreover, to increase the weight which has to be carried by the chassis, and this also may be expected to have an equivalent effect. The fuel allowance is reduced from a gallon for each $22\frac{1}{2}$ miles to a gallon for every 25 miles, and the weight of body, passengers, and ballast (now lumped together) is to be 1,100 lbs. as against 950 lbs. As concerns the speed capabilities, further new conditions have been imposed; though, apparently, their object has equally been that of making the competing cars even more suitable for ordinary private use. We refer to the gear-box restrictions, and to the specified height of the backs of the seats from the ground. Not only are more than four forward speeds prohibited, but every car has to show that it is not geared abnormally, for it will be called upon to ascend a hill of 1 in 6, and also to run at as low a speed as 12 miles per hour on the level with its top gear in use. The height of a seat is calculated to have a material effect on the "windage" of a car, a matter that seriously affects speed capabilities.

♦ ♦ ♦ Freaks Eliminated.

OTHER regulations now incorporated apparently aim solely at limiting the event to *bona fide* pleasure cars, one of these being that certain momentary stops are to be made at specified points, and another being that the chassis length has been increased (from 6 ft. 6 ins. to 7 ft. behind the dash). The former can obviously be taken further advantage of, if necessary, since that certain dangerous spots on the route could thus be virtually neutralised. Somewhat in the same category, moreover, though slightly different in that they also guard against certain evasions of the rules, is the regulation rendering it incumbent on the manufacturer to arrange the body quite independently of all pipe connections or wires, and in fact not only to have an easily removable body, but to make the chassis absolutely complete in itself. There are, moreover, a series of important restrictions that affect the construction and arrangement of the entire fuel system, while one precautionary measure that will unquestionably be welcomed by all competitors, saddles the officials with the duty of cutting open the fuel tanks on the first three cars after the race. Freaks are to a certain extent guarded against by one "discretionary" clause, and by another clause that prohibits exhaust-relief-valves or ineffective silencers. But, generally speaking, the rules, as amended, are now fairly adequate for eliminating freaks, in themselves.

♦ ♦ ♦ Steam Cars Admitted.

THE most radical change, however, and one which cannot but give universal satisfaction to all, since it is the first serious attempt that has been made to overcome a great difficulty, is that which allows steam cars 50 per cent. more fuel than petrol cars, and allows them to use whatever liquid fuel they prefer. Even if, with this allowance, it is unlikely that a steam car could at present secure the coveted trophy, the effect of the new rule will nevertheless be of value, for it will render available much valuable data that can be taken advantage of for future occasions. In view of the strong feeling that has—however reasonably or unreasonably—arisen in certain quarters on this very question, we congratulate the club on having now taken the bull by the horns, and on

having made an official statement on the subject. This statement is contained in the following explanatory resolution which, by the express desire of the Technical Committee, should be read in conjunction with the new rules. It reads as follows:—

Owing to the many radical and inherent differences between internal combustion engines and external combustion engines, and to the lack of sufficient comparative data on the subject, it is, in the opinion of the Technical Committee, impossible to arrive at any accurate basis by which steam cars can now be placed on precisely parallel footing with petrol cars in the Tourist Trophy race. In view of the strong desire of the club to induce owners and manufacturers of steam cars to take part in that event, they feel justified in now adopting for the 1906 race, a purely arbitrary basis of comparison, whereby it is estimated that the power of the engines, and, consequently, the speed capabilities of the steam car, may be expected to approach to those of the petrol car.

In conclusion, we cannot avoid expressing our satisfaction that many of the conclusions at which we arrived in the series of articles we devoted to the subject, even prior to this year's race, have been proved to be so near the mark, and so correct in general tendency by being thus largely embodied in the rules for next year's Tourist Trophy. It was, of course, a foregone conclusion that numerous modifications would have to be made to the original rules after the first race of the kind had been held, and it is evident now that the Races and Technical Committees have not only taken full advantage of this year's experiences in the Isle of Man, but have also been able to bestow very mature consideration on all the many general questions involved.

♦ ♦ ♦ The C.T.C. on the Right Side of the Fence.

A CONSIDERABLE proportion of the cycle interest is somewhat hostile to automobilism. We are accordingly pleased to find the *Cyclists' Touring Club Gazette*, which represents the aristocracy of cycloedom, taking up a very judicial attitude in regard to the Royal Commission on the Motor Car Acts. On the whole the organ of the C.T.C.—they have, we believe, a considerable number of motor cyclist members—is on the automobile side of the fence, and the club has given evidence before the Commission, though, of course, we do not know what the evidence was. In order to help us form a guess, however, the *C.T.C. Gazette* has kindly outlined its position in its last number. From this we learn with satisfaction that the club will not oppose the abolition of the speed-limit, as "in their opinion it has quite failed of its object." We never quite knew what its object was, but we are glad to find it has failed in it. The C.T.C. also puts forward some recommendations designed in the cyclist interests to replace, or, at any rate, supplement, the clause about driving to the public danger. These are that it should be an offence to jamb a cyclist into the hedge—a very proper provision, though it is not expressed quite like that—that any motor car driver who raises such a dust as to create a nuisance or goes round a corner at high speed on the wrong side of the road, shall be guilty of offences. It is also pleasing to note that the C.T.C. are as much alive as ourselves to the horrible nuisance occasioned by small boys who, having by some means or other become possessed of a bicycle, rig out the same with a motor car hooter, and so induce nervous pedestrians to jump out of the way under the expectation that a high-powered automobile is in full progress upon them. We hope the C.T.C. will be decided on this question, and that their activity may result in the incorporation of some such provision in the next Motor Car Act.

THE 1906 LEGROS AND KNOWLES "IRIS" CARS.—PART I.

Fig. 1.—The new Legros and Knowles "Iris" Chassis. View, from the "off" side, of the 25-30-h.p. Model.

EVEN at the Olympia Exhibition last February, when the first Legros and Knowles chassis made its public appearance, it was at once recognised—by engineers at any rate—that those responsible for it had made a very close study of motor car construction, and had very fully grasped the many important problems that are involved in up-to-date automobile design. The Legros and Knowles stall therefore proved itself to be one of the chief attractions of that particularly successful Show. Most motorists realised that another first-class British

make of car would shortly be available, and that the home industry was becoming more and more capable of holding its own. Good as was the chassis then exhibited, the 1906 touring cars, of which we now give full particulars, are, in numerous respects, far better, and it therefore goes without saying that the new 4-cylinder models are well worth the close attention of all.

It is the two touring models with which we are chiefly concerned at present, and these are, to all intents and purposes, identical except in size. A very good, general

Fig. 2.—View, from above, of the 1906 "Iris" Chassis, for Pleasure Vehicles, showing the new Engine, which is carried by two, transverse, tubular members of the frame, the 3-point suspension Gear-Box, the special Universal-Joints on the Propeller-Shaft, and the "live" rear-axle with its Foot- and Hand-operated Hub-Brakes.

D

Fig. 3.—The 1906 Legros and Knowles Chassis. View showing the distinctive appearance of the new 25-30-h.p. and 35-40-h.p. Touring Cars—the shape of the Radiator, the position of the Circulating-Pump, and the special construction of the Tubular Front-Axle.

indication can, however, be given of the direction in which their development has proceeded during the year, if we refer for a moment to the commercial and the marine work which the firm also have in hand; the very substantial engine which was used on the 1905 pleasure vehicle is now only employed for 'buses, luries, and—in a suitably modified form—for boats. A special feature is being made of the "Iris" double-deck 'bus, which seats 36 passengers and has a worm-driven live-axle, while the same chassis lends itself admirably for other types of heavy vehicle.

Reduction of weight is, indeed, the first thing that strikes the casual observer when looking at the latest pleasure cars, for last year's model was, it will be remembered, unusually heavy, and very little attempt had then been made to keep the weight down. Even the new vehicles, however, are far from being unduly light, and a careful comparison between the two models shows that neither strength, durability nor accessibility have been sacrificed to any appreciable extent. The earlier car was very fully described in our May issues.

Such comparison brings to light the fact that the new chassis differs entirely in almost every way from that of last year. It has, for instance, a bevel-driven live-axle instead of side-chains, the rear springs are of the full

elliptic, instead of semi-elliptic pattern, and all the brakes act direct upon the hubs of the road-wheels.

To begin at the beginning, however, it should be mentioned that one of the chief aims of the designers has been that of securing absolute silence at all times. Not only, therefore, have the exhaust gases been effectively muffled by the provision of two consecutive exhaust-boxes, but the gearing has been rendered as noiseless as possible, and steps have otherwise been taken to prevent any portion of the mechanism from rattling. Another point to which attention should be directed, before passing on to matters of greater detail, is that a very distinctive external appearance has been obtained for these cars. This is, in small measure, due to the rear springs, already referred to, but has been chiefly brought about by the unusual form of the radiator and bonnet. As seen in our illustrations, the car is diamond-shaped when looked at from in front, and the bonnet, which is made out of one metal sheet and is hinged centrally to the dash, slopes down very sharply from the central ridge at the top.

The Special Features.

Other special characteristics, which in accordance with our usual practice will be briefly enumerated in advance, for the benefit of those who do not care to enter into greater detail, are as follow :—

Fig. 4.—Rear View of the new "Iris" Chassis, giving an excellent general idea of the special Live-Axle construction—which enables the Differential-Gear to be removed easily—the full Elliptic Side-Springs, and the double Brake-system for the Driving Wheels.

(1) Even the cam-shaft on the engine has ball-bearings, and, therefore, the sweeping statement may be made that ball-bearings are fitted to all shafts, with the solitary exception of the crank-shaft.

(2) A single lever above the steering-wheel serves to control the power and speed of the engine, which is otherwise ungoverned; this lever simultaneously advancing or retarding the time of ignition, and opening or closing the throttle-valve.

(3) The engine itself is of very simple design, with induction-pipe passages formed across inside the castings that constitute each pair of cylinders; all the valves, which are interchangeable, lie alongside one another, and not only can the base of the crank-chamber be removed without disturbing the crank-shaft, but, in much the same way, the entire cam-shaft with its oil-tight casing can be detached from the engine.

(4) Great care has been taken to render the water pump accessible from the front of the vehicle, and for this reason it has been fixed to the radiator, where it is gear-driven by the engine.

(5) Only one pipe is used for feeding the engine with oil from the pressure-fed lubricator on the dashboard, and this dashboard fitting has combined with it the two-way switch for the ignition system (and for the carriage lamps); in this way it is impossible for a careless driver to run the engine without oil, and it is also impossible for the engine to be flooded with oil when the switch is turned off.

(6) Ignition is effected with a single trembler coil, in conjunction with a high-tension distributor, placed beneath the bonnet.

(7) A main clutch of the multiple disc type—the "Bradley" pattern—is employed, this having, as our readers are already aware, metal-to-metal friction surfaces contained in an oil bath.

(8) Three forward speeds and a reverse are provided by a gear-box of the sliding spur-wheel type, which gives a "direct-through-drive" on the top gear, and is fixed to the frame at three points only.

(9) A very remarkable form of universal joint has been adopted for both ends of the propeller shaft, this consisting of three flat plate members, which are made of spring-steel, and afford all the flexibility that is required. The plates are connected together across alternate opposite corners, and they have the effect of providing a universally flexible coupling, that has no rubbing friction surfaces.

(10) Quite the most important portion of the chassis is the live-rear-axle, for not only are the road-wheels

mounted quite independently about the stationary axle tube, but the axle is so designed that the differential-gear, together with the bevel wheels that drive it, can be removed without otherwise dismantling, or taking off, the axle; the axle is connected to the main-frame by radius rods at each side, as well as by a central torque-rod, and there is to be a simple device for relieving the springs of all side strains. The interior arrangement of the axle is such that bevels of different size can be employed to suit the individual requirements of all users.

(11) Two brakes, side by side, are fitted to the hubs of the driving wheels, and the operating and compensating mechanism by which one on each hub is applied by hand, and the other pair by foot, is carried alongside the axle-tube; all four are of the external, contracting type, and all four brake-bands are held steady by springs that prevent them from chattering.

The Chief Dimensions.

The smaller car has a 25-30-h.p. engine, the cylinders of which have a $4\frac{1}{4}$ -in. bore and a stroke of $5\frac{1}{4}$ in. At a speed of 800 revs. per min., it develops 25-h.p., while the higher quoted power (30-h.p.) represents its output at a speed of 1,100 revs. per min. The corresponding cylinder dimensions of the engine on the larger vehicle are 5 in. and $5\frac{1}{4}$ in. respectively, this engine being rated at 35-40-h.p. since its output corresponds with those figures when running at 750 and 1,100 revs. per min. respectively.

Both cars are designed to take side-entrance bodies, with seating capacity for five persons, and both chassis have the same wheel-base, track, and tyres. The wheel-base is 9 ft. 6 in., the track 4 ft. 5 in., the front wheels have 815 by 105 mm. tyres, and the driving tyres are 820 by 120 mm.

As already pointed out, the design of the chassis is practically the same in both cases, the only difference being in point of size of the various parts. The photographs that we give of the 25-30-h.p. chassis, in Figs. 1, 2, 3, and 4 are, therefore, almost equally applicable to the 30-40-h.p. model. Fig. 1 is a view from the "off" side, Fig. 2 is taken from above, Fig. 3 is a front view, and Fig. 4 shows the chassis from the rear. The actual machine from which they were taken was fitted, temporarily, with a clutch of the internal cone type, instead of its proper multiple disc clutch, so that, in this respect, the chassis shown differs slightly from standard.

(To be continued.)

Royal Commission on Motor Cars.—At the regular sittings of the Commission, the latter part of last week and the early part of this week, under the presidency of Viscount Selby, amongst the witnesses examined have been the following:—Mr. Alexander Govan, manager of the Argyll Motor Works, Glasgow; Sir William Vincent and Mr. W. H. B. Holton, on behalf of the County Councils Association; and Mr. D. Crichton, hon. secretary of the Roads and Traffic Reform Association; Mr. A. Campbell Swinton, chairman, London and District Motor Omnibus Company (White Arrow line); Mr. Clarence Freeland, managing director of the London Motor Omnibus Company (Vanguard line); Mr. E. C. Sanders, clerk to the Liverpool Justices, on behalf of the Incorporated Justices' Clerks' Society; and Mr. H. H. Copnall, clerk to the

Nottinghamshire County Council, on behalf of the County Councils Association; Captain Sant, the Chief Constable of Surrey; Superintendents Moore, Powell, and MacIntyre, of the Metropolitan Police; Captain Fullarton James, Chief Constable of Northumberland; Dr. Williams Freeman, of Weyhill, Andover; and Mr. T. W. Grace, President of the Manchester Automobile Club.

THE Automobile Association Cyclist Patrols were on duty last week end from Purley Corner to Patcham on the Brighton Road, from Kingston to Hindhead on the Portsmouth Road, and from Hurstbourne Priors to Wallop Cross on the Andover Road. These patrols, officially appointed, always carry a yellow badge—the same colour as the cover of THE AUTOMOTOR JOURNAL—either on the arm or under the coat.

MULTI-CYLINDER ROLLS-ROYCE CARS— TWO 8-CYLINDER MODELS.

FROM one to two in the very early days, from two to four a little later, from four to six comparatively lately, and now from six to eight. Such practically sums up one of the many lines of development traversed in the history of petrol cars—remarkably rapid development, too, as all our readers are aware. Although not entirely a novelty, since more than one engine of a somewhat similar type has already appeared on our pages, the new 8-cylinder engines now being put on the market by Messrs. Rolls and Co. are bound to create quite a sensation amongst motorists, particularly as they form the chief feature of two of the standard 1906 Rolls-Royce vehicles that are to be shown at Olympia. Both cars, moreover, demand attention from other points of view, as well as from that of the engines, for one is intended to appeal to those for whom electric carriages have special attractions, and the other has been designed as a touring car for running at

is
di
b

and they both have leather-faced cone-clutches. The landaulette, which seats six persons, naturally differs more from ordinary cars than does the 3-seated "Legal-limit" phaeton, and thus it is that its chassis—of which a good side view is given in Fig. 1—has several unusual features, of which the position of the engine is but one. The steering-gear, for instance, has a bevel-gear device introduced into the column that carries the wheel, so that the lower end of the shaft passes rearward, at right angles to the upper portion of the steering-pillar. This vehicle has a 7 ft. 6 in. wheel base, and 820 by 120 mm. tyres, whereas the other new model has an 8 ft. 10 in. wheel base and 810 by 100 mm. tyres. Both cars have a transverse spring at the rear, in addition to the usual semi-elliptic side-springs.

Our other illustrations all refer to the engine, these

Fig. 1.—Side view of the 8-cylinder Rolls-Royce Landaulet Chassis, showing the ingenious arrangement of the Bevel-gear in the Steering-pillar, and the position of the Engine beneath the driver's feet.

has thus been possible to give to the "Landaulet" the same external appearance as the well-known electric vehicles which are naturally so much in vogue in London, and the smooth running resulting from the use of so many cylinders still further completes the resemblance between the new car and those carriages. The engines are but little longer than an ordinary four-cylinder engine, they require less head room, and they materially exceed the usual dimensions in point of width only, because the cylinders are fixed diagonally—four on each side—to the crank-chamber, all sloping outwards at 45 degrees from vertical. The power available is about 20-b.h.p. at a speed of 1,000 revs. per min., and, since the cars are geared to only 26 miles per hour on the "direct-drive" top-gear, it is comparatively seldom that the change-speed-mechanism has to be manipulated. The three forward speeds, provided by sliding spur-wheels, represent 11, 18, and 26 m.p.h., respectively, both cars are of the chainless type, with "live" rear-axes,

photographs and drawings having been supplied to us by Messrs. C. S. Rolls and Co. Taken in conjunction with one another, they give a good general idea of its construction, even though in some respects the details are not as clear as might be wished. The views in Figs. 2 and 3 are taken more or less from the front, Figs. 4 and 5 from above and beneath respectively, Fig. 6 is a side elevation, and Fig. 7 is an end elevation (partly sectional). Fig. 8 is a side view, and happened, at the time the photograph was taken, to be fitted with a second set of ignition-plugs, for the purposes of determining the best position for them in practice.

Each cylinder-casting, of which there are four, constitutes a pair of cylinders, complete with their jackets, heads and valve chambers, and these are all bolted in much the usual way to the upper half of the crank-chamber. Instead of lying vertically, however, their axes are set at an angle of 45 deg. to the vertical, and thus the four cylinders on the one side are at right

Figs. 2 and 3.—Two views showing the front end of the Rolls-Royce 8-cylinder Engine, with the enclosed Governor (F) above—and the gear-driven Oil (E) and Water (D) Pumps beneath—the casing containing the entire gearing.

angles to the four on the other side. The cylinders on the two sides are moreover not quite opposite one another, but are slightly staggered, as seen in Fig. 4. This enables straight connecting-rods to be employed, and all the big-ends are quite independent of each other on their crank-pins. An important point in connection with an engine of this design is that although the crank-shaft receives a regular series of impulses—one for each quarter revolution of the shaft—yet the crank-shaft itself is quite a simple forging, and all the crank-pins are either in line with one another or immediately opposite one another; the shaft is, indeed, precisely similar in shape to that for an ordinary 4-cylinder engine.

In spite of the diagonal positions of the cylinders, the valves, all of which are interchangeable, are placed vertically, as in an ordinary engine, those on the one side of the engine being operated by one enclosed cam-shaft, and those on the other side by a similar cam-shaft. Incidentally, this disposition automatically gives the very advantages that have been specially secured by some makers of vertical engines in the past, for the valve

chamber is brought more closely up to the cylinder proper, and consequently the wall-surface of the combustion-chamber walls is reduced in area (see Fig. 7); hitherto, it will be remembered, it has been the valves that are set at an angle to the cylinders instead. Above each valve is the usual inspection plug, and, passing through the wall of each valve-chamber is the horizontal ignition plug, C; the inspection-plugs above the inlet-valves are marked A in our illustrations, and those above the exhaust-valves are indicated by the letter B.

Except for its unusual shape, the crank-chamber is made in the same way as that of most engines, and the spur-wheels by which the two cam-shafts are driven are enclosed in an oil-tight casing in front. There are, however, gear-driven vertical shafts passing through this same chamber also, and these drive the water-pump, D (on the under-side), the lubricating-pump, E (also beneath), and the governor (inside the casing, F, above). The pump, D, forces the water through the pipes, D¹, into the base of all four cylinder-jackets, whence it is led back to the radiator by the pipes, D². Similarly,

Figs. 4 and 5.—Top and bottom views of the Rolls-Royce 8-cylinder Engine. In the former, the simple Pipe-connections for the Water and for the Carburettor are prominent, while the latter clearly shows the Oil (E) and Water (D) Pumps, for lubricating and cooling the Engine.

Figs. 6 and 7.—Side elevation and end elevation (partly in section) of the 20-h.p. 8-cylinder Rolls-Royce Engine. In Fig. 7, the shape of the Combustion-chambers is clearly indicated, and the arrangement of the Cam-shafts is also rendered evident.

the pump, E, draws its supply from the well, E', in the base of the crank-chamber, and delivers it to all the bearings of the engine, the oil ultimately finding its way back again to the well. For the lubricating system the crank-shaft has oil-holes drilled through it; for regulating the pressure in the feed passages, a relief valve is fitted, this valve allowing any surplus oil to escape back direct to the well, as soon as the necessary pressure has been attained. In this manner, an entirely automatic feed is obtained, and the engine at all times receives a constant supply of oil.

Projecting horizontally, just below the governor-casing, F, is the horizontal shaft, C', that is caused to rock about its axis by the governor, and is connected up to operate the throttle-valve, A'; part of this mechanism is, however, missing in our illustrations. The vertical governor-shaft projects up through the top of the casing, F, and it is for the purpose of driving the combined commutator and distributor (for the ignition) system that it does so. This ignition apparatus, which is fixed independently in the chassis and is driven through a universally-jointed shaft, is shown from two different points of view in Figs. 9 and 10.

It is used in conjunction with two trembler-coils, one of which serves for each set of four cylinders, and it not only completes the circuit between the battery and the low-tension windings of the coils, but also distributes the high-tension current to the ignition-plugs. In Figs. 9 and 10, the low-tension contact-drum, C', with its two carbon contact-brushes, is visible outside the casing, C', and the high-tension terminals for the distributor are seen in place on the casing. The terminals,

C', are those to which the independent secondary windings of the two coils are connected, and those marked C' are the terminals from which the eight wires are led to the two sets of four plugs.

The time of ignition can be varied by the lever, C', which acts upon a spiral key-way device contained inside the casing, C'; by this mechanism the revolving member of the distributing commutator is caused to rotate relatively to the governor-shaft, and hence the time of ignition can be varied, although the casing, C', remains stationary.

In Fig. 8 the position of the carburettor, A', will be noticed, as also the branched induction-pipe, A', by which it is connected with the inlet-valves. The throttle-valve, A', lies centrally above the crank-chamber, where the separate induction-pipes join up together (see Fig. 4).

The cylinders themselves are of small size, the bore and the stroke being only $3\frac{1}{4}$ ins.; the reciprocating parts are consequently sufficiently light to permit of high-

speed running without any undue vibration. At its normal speed of 1,000 revs. per min., the engine develops about 20-b.h.p.

As already mentioned, one ignition-plug only is provided for each cylinder, although two are seen in Fig. 8. That particular engine was so fitted in order that the best position for ignition could be determined, and a decision could be arrived at for standard practice in future. It is interesting to know that the horizontal plugs passing through the wall of the valve-chambers was found preferable to those projecting direct into the centre of the combustion-chambers.

Dagonet on Municipal Trams versus Motor Busses.—The paragraphs which we reproduce below are culled from Dagonet's "Mustard and Cress" column of the *Referee*, which, as everyone knows, is the usual weekly contribution to that paper of Mr. G. R. Sims. Mr. Sims, as is hardly necessary to observe, is one of the most far-seeing and level-headed writers in London. It would be impossible, as our readers will observe, to put the case against the indefinite extension of trams with greater cogency or force. We reproduce Mr. Sim's views with the greater pleasure as they so entirely accord with those expressed by us time and again during the past seven or eight years:—

"I AM as fond of tram rides as anyone, and quite as fully alive to the advantages of cheap locomotion as any Progressive gentleman on the L.C.C. who has tramways on the brain, but I cannot let my tram worship blind me to the peril looming ahead.

"I am convinced that within the next ten years many of the tramway lines laid down at the ratepayers' expense will have to be taken up because they will be hindrances to the development of traffic. In some of the outlying districts of London the tram lines are already sources of constant local inconvenience. Look at the deadlock on Kingston Bridge.

"It has been decided to run a tram line from the Marble Arch to Cricklewood. Why? To join up with the trams that run from Cricklewood to Edgware. But there is absolutely no necessity for the expense or the interference with traffic which the laying of the tram lines will mean. The Vanguard and Victory motor 'buses run from the corner of the Edgware Road to Cricklewood every few minutes all day long.

"The tramcar stops at almost every lamp-post. The journeys are slow and irritating in consequence. The motor 'bus, on the contrary, travels rapidly and with few stoppages, and can dodge in and out of the traffic and get ahead of everything. It is as sensible to lay new tram lines in and around the Metropolis now as it would be to stretch overhead ropes across the streets to hang oil lamps on.

"The luxury on some of the new tram lines intended mainly for the working-classes is a specimen of the recklessness of those who trade with the ratepayers' money. The cars are palatial in their appointments. They are upholstered in velvet, the windows are expensively curtained, the electric fittings are worthy of a Park Lane mansion, and the woodwork is of the daintiest description, and most artistic construction.

"I sat in one of these cars the other day next to a poor hawker and his wife. The woman gazed for a moment in silence at the surroundings in which she found herself, and then she turned to her husband, and exclaimed with a sigh, 'Oh, Bill, how can we go back to our 'umble 'ome after this!'

"I would not say a word against this extravagance of the municipalities in the matter of the tram service if I did not feel that the motor 'bus is bound ere long to compete with them, and to beat them in the matter of popularity. Moreover, the tram line always depreciates the value of the property through which it passes. The motor 'bus improves it."

"Police-trap" or "Motor Car trap"?—Everyone has had a little fun about the precise magistrate of Kingston who objected to the expression "police-trap," and explained to a trembling defendant that he was not justified in using this expression, but that what he undoubtedly meant must be "motor-trap." "If you set a trap to catch rats," said the magistrate, "that is a rat-trap." Apropos of this, the *Daily News* has become facetious, and positively suggests that upon the magistrate's principles of phraseology, a constable whose business it is to detect and bring to justice hooligans, ought to be called a "hooligan-constable." It is a sign of the times to find a paper which has not been characterised by appreciation of the automobile movement venturing to suggest that such a conception as a hooligan-constable is a possibility.

FIG. 9.—The Bassée-Michel High-Tension Magneto (1906 Type).—View of the special Switch which forms part of the apparatus and enables a battery of accumulators to be instantly brought into use, instead of the magneto, when necessary. The view on the extreme right is taken from behind, and shows the permanent inter-connections.

diagram in Fig. 7 shows all the necessary connections. All the terminals on the actual apparatus are stamped with the same letters or figures as are used in this particular diagram, which is, therefore, self explanatory. The letter E, however, has been introduced in order to indicate which parts it is necessary to "earth" by connecting them to the frame of the car. Generally the magneto is "earthed" by the bolts used to secure it in place, but where it happens to be supported by the dash or floorboards, so that it is not in actual metallic contact with the frame, then it will be necessary to effect this connection by a wire. It would be better, however, to join the "earth" wire from the battery, to the magneto frame, instead.

With a separate coil system, it is not necessary to provide a special switch for short-circuiting the armature, as it is when the secondary winding is wound on the armature itself.

The Battery Circuit.

Most motorists nowadays like to have their cars fitted with an alternative ignition system, and in comparatively few instances are they willing that their cars should be unprovided with a set of accumulators. With the 1906 Bassée-Michel system the installation of battery ignition is a particularly simple matter, and all that the owner has to do is to purchase the accumulator; the coil, switch and distributor are already provided, and what is more, are essentially designed for such use. When the battery is in action, it is connected to the small-resistance primary coil which has been specially wound

to be suitable for working direct on four-volts. As there is no trembler, the contact-breaker on the magneto is used instead, but this is, as we have explained already, connected in the circuit of this coil. All that is necessary, therefore, when changing over from one system to another is to turn the switch. It should be borne in mind, however, that a contact-breaker is not the same current-saving device that the trembler is, and motorists should naturally not use the batteries unnecessarily.

OUR attention has been drawn to the fact that the "M. and B." steering-gear, of which we gave an illustrated description the week before last (Oct. 28th), is similar in many respects to that of the Albany Manufacturing Co. The latter mechanism was shown in equally full detail by us on page 228 of our issue of Feb. 20th, 1904, and those who may take sufficient interest in the subject have, therefore, an excellent opportunity of comparing the two designs. The Albany Co. inform us that their steering-gear was patented by them in 1901 (the number of the patent being 21071), and they appear to consider the "M. and B." mechanism to be an infringement of that patent; naturally, however, this is not a matter that has any direct bearing for the majority of our readers, nor is it one upon which it is necessary for us to express an opinion.

It is satisfactory to find that the inquest into the sad accident that occurred near King's Cross Station, in which Lord Rosebery was the occupant of a car belonging to Mr. Leopold de Rothschild, which ran over and killed a young woman of the name of Brown, has resulted in complete exculpation of the driver of the car, the verdict being "accidental death." Special interest attached to the proceedings, owing to the fact that Lord Rosebery came forward to give evidence on behalf of the driver. It appeared that Miss Brown, after starting to cross the road, a short distance in front of the car, vacillated, as so many women do when they see a vehicle approaching, ran to and fro, turned towards the car and then, when too late, started to walk forward again. It is one of the most fruitful causes of accidents, and the most difficult for drivers to guard against.

HIGH-TENSION MAGNETO IGNITION.—Continued.

THE GIANOLI SYSTEM.

Introduction.

THE Gianoli System is one of those in which the magneto is of the real high-tension type; that is to say, the secondary winding is wound direct on the armature itself, and no use whatever is made of any separate external induction

therefore, when the same current strength has been arrived at, no matter how fast the magneto may be driven.

In this way it serves the important function of a voltage controller (or pressure regulator), since it neutralises the effects of any excessive voltage which may be generated in the armature at very high speeds. The faster the armature turns, however, the earlier will the contact-breaker come into action—since the voltage rises more quickly—and it follows, therefore, that the device also constitutes an automatic “advance” and “retard” for the ignition. In practice, however, this is naturally not relied upon entirely, since obviously it could not meet all requirements on any car. Hand-timing is, therefore, provided in addition, and here, as elsewhere throughout the construction of this machine, an extremely simple and effective method has been devised. For the purpose, the magnets have been provided with adjustable pole-pieces, and these are connected to the timing-lever so that they may be rocked about the armature. Altering the position of the pole-pieces is, of course, equivalent to tilting the magnets, or re-setting the armature relatively to the engine—as is done in the Eisemann system—and it has the same effect of advancing or retarding

FIG. 1.—The Gianoli High-Tension Magneto.—View showing the machine complete; and also the High-Tension Distributor, which in this system forms a separate unit—designed to be driven by the engine, like an ordinary “commutator.”

coil. This in itself is nothing unusual, but the Gianoli System has, nevertheless, many peculiarities in detail, which render it not only distinctive, but also very important from the user's point of view.

Foremost among its features, is the extreme simplicity of the magneto itself—in fact, as a unit, it is the most simple of all the high-tension machines which have hitherto come before our notice. This simplicity is mainly due to two departures from orthodox practice, *viz.*, the substitution of an automatic contact-breaker for that of the mechanically-operated type, and the transposition of the high-tension distributor from its accustomed place on the magneto to that usually occupied by the “commutator” on most engines. The introduction of the automatic contact-breaker is, however, not primarily done with a view to increasing the simplicity of the machine as a whole, for there are other important benefits in connection with this device, which enable it to play an important part, electrically as well as mechanically, in the individuality of the Gianoli System. This contact-breaker is actuated by the magnetism induced by the armature current—in much the same way as a trembler on an ordinary trembler coil—and it comes into play,

the ignition as have these other earlier methods. It has, too, the advantage of providing a practically unlimited

FIG. 2.—The Gianoli High-Tension Magneto.—View of the machine partly dismantled to expose the Armature in position between the Magnets; also showing the adjustable Pole-pieces, G^1 , by which the time of ignition is varied.

range, and in this respect differs from those systems in which only the contact-breaker is rocked over, relatively to the armature shaft, in order to "time" the spark.

The continued preference, at the present day, for fitting two systems of ignition to cars has led the manufacturers of the Gianoli magneto to make provision for the alternative use of an ordinary battery and coil by combining a mechanical contact-maker with the high-tension distributor, so that that member may form a complete unit for use with the accumulator system as well.

In constructional detail, as well as in the design, there are several points of interest, and in the new models which are now being made to the specifications of Mr. McCormack there will be even further improvements. It is interesting to note—and it is an important fact in favour of the magneto—that the Gladiator cars for next year are, amongst others, being fitted with them. Mr. McCormack has now formed an English agency for the independent supply of these machines for any type of car.

Our Illustrations.

All the more interesting features of this machine are shown in our illustrations. The magneto complete is seen in Fig. 1, and the same view also shows the separate distributor which is used with it. In Fig. 2 the front bearing plate and high-tension collector have been removed to expose the armature *in situ*, while separate views of the armature, adjustable pole-pieces, and magneto are seen in Fig. 3. A sectional line drawing, showing the general arrangement of parts, is given in Fig. 4, and the illustrations in Fig. 5 show, in detail, the construction of the automatic contact-

breaker, the theory and action of which is diagrammatically illustrated in Fig. 6. Separate views of the high-tension distributor are given in Fig. 8, in order to show its construction more clearly than is possible in Fig. 1. Diagrams, illustrating two important and interesting points in connection with the action of the automatic contact-breaker also appear in Figs. 7 and 9, but these will be described in due course. The Gianoli system is, as we have already mentioned, adapted for the alternative use of battery ignition, and the special coil-box and switch, which are supplied for this purpose, are illustrated in Figs. 11 and 12. The internal electrical connections of this box are shown in Fig. 13, and a diagram of connections for the Gianoli system (magneto only) is given in Fig. 10. The scheme of wiring for the two systems combined is diagrammatically shown in Fig. 14, and this, in itself, is sufficient to enable any motorist to make, or check, the connections on his car.

The Magnets.

There are two peculiar features in the construction of the magnets. The first of these is the adjustable pole-pieces, which have been referred to before, and the second is the method of securing the elements in place without drilling them. In form, the magnets are of the usual compound horse-shoe type, and they are composed of six separate units, or elements. The inner members are somewhat shorter than the outer members, in order that they shall accommodate themselves to the steps, or ledges, which are cut in the fixed, cast-iron pole-pieces, G^3 , on which they are mounted. This particular arrangement is very clearly indicated in Fig. 3, and it will be noticed that even the outer members rest directly on the pole-pieces, G^2 , and not on the base-plate, G^1 , as is the more usual practice. This enables them to be rigidly secured by means of the brass-straps, G^6 , which are screwed directly to the pole-pieces, G^2 . The pole-pieces, G^2 , are themselves bolted to the base-plate, G^1 , in the usual way, and the various members thus form a rigid unit, without it having been necessary to drill holes in the magnet limbs. M. Gianoli lays great stress

on this point, and claims that, by keeping the limbs intact, he is able to obtain more powerful magnets and at the same time render them less liable to demagnetisation while the machine is in use.

The adjustable pole-pieces, which enable the magneto to be "timed" by hand, are formed by a pair of cast-iron shields, G^5 , similar—except for the fact that they do not revolve—to those used on the Simms-Bosch magneto for another purpose. These shields are carried by the main-bearing-plates, M and M^1 , which are themselves mounted so

that they are free to be rocked about the armature-spindle, which they also support. The adjustable pole-pieces, G^5 , make an easy sliding contact against the fixed pole-pieces, G^2 .

(To be continued.)

THE Middlesex County Council have issued a report from which we gather that the sum of £3,174 11s. was received during the last financial year under the Motor Car Act in fees for the registration of motor vehicles and licensing of drivers. The figures are made up as follows:—Motor cars, 1,076; heavy motor vehicles, 21; motor cycles, 1,300; driving licences (including renewals), 5,997; duplicate licences, 79; copies of entries supplied from the register, 82; transfers of ownership registered, 422; and manufacturers' marks issued (including renewals), 64.

SPEED INDICATORS FOR AUTOMOBILES.—PART VII.

(Continued from page 1104.)

he circular case, A, contains the copper ring, E, to instead of the centre, of it can thus be placed it now extends (Fig. 1) the dial.

Fig. 1.—The Gratz Speed Indicator (1906 Model).—View showing the instrument complete with its driving mechanism. The distinctness of the scale, and the even spacing of the divisions, are prominent in this view.

THE GRATZE SPEED INDICATOR (1906 MODEL).

IN principle, the new model of the Gratz Speed Indicator—for which the British Electric Equipment Company now have the sole agency—does not differ in any way from the previous instrument which we described in our columns on October 29th, 1904. There has been considerable modification in design, however, although externally it has much the same appearance as before.

It will be remembered that the Gratz Indicator is of the electro-magnetic type, but that it is entirely independent of electrical wires of any description both inside and outside the instrument proper. In being thus self-contained it resembles, outwardly, rather the indicators of the mechanical variety than those in which the electro-magnetic element is distinct from that portion which carries the dial. In the previous model a permanent magnet was rotated about a pivoted copper ring, in such a way as to cause that copper ring to try and revolve in unison with the magnets. The copper ring, however, was prevented from actually revolving through being anchored by a hair spring, but it was free to twist round to a certain extent, and it carried a pointer attached to its spindle, which indicated the speed of the car on a suitably arranged dial. Inside the copper ring was a stationary iron armature or "keeper," which served to concentrate the magnetism along the path intended for it.

In this year's model—illustrated in Figs. 1 and 2—the only radical change is that the armature is now rotated instead of the magnets; practically everything else—so far as the speed-indicator proper is concerned—remains the same as before.

The advantages obtained from this change are considerable, not the least important being that the permanent magnet can now be more effectively supported, since it no longer revolves, and it can, besides, be made in a shape and size more suitable to the general design of the instrument.

In Fig. 2 the latest model is shown in detail, and it will be noticed how conveniently the magnet, C,

KLEE'S TANGENTIAL STEERING-GEAR.

THIS steering gear, the invention of Mr. H. Klee, has been designed to overcome a slight inherent inaccuracy in ordinary systems which have their front wheels interconnected by one tie-rod of definite and invariable length. These errors and their consequences were very fully explained in an article which appeared in our issue of April 23rd, 1904, and we do not purpose to deal at length with this side of the question again now. Our readers will remember, however, that when a car is

$$c = e \sin \beta$$

$$d = e \sin \alpha$$

In the above equations the value of e is equivalent to the radial length of the steering-knuckle as indicated in Fig. 1. The angle, α , is the angle which that radius, on which the particular length, d , is about to be measured, makes with the zero line; these values are marked on Fig. 2 for every 10 degrees. The angle, β , depends on the

Fig. 1.—Elevation and Plan of Klee's Tangential Steering Gear, showing the arrangement of the cam-plate, D, which operates the divided tie-rod, C.

travelling round a curve, there is a risk that one or both tyres may be dragged over the ground because the two wheels are not set at the correct relative angles.

In the Klee steering-gear, Fig. 1, the tie-rod, C, is divided, and each half is independently operated by a cam-plate, D, mounted on the axle, A, and connected by a worm-gear, D², E¹, with the steering-rod, E. The tie-rods themselves are also partly mounted on the axle, in which a slot, A¹, is cut in order to form a guide for them. The manner in which they operate upon the steering-knuckle, B², of the stub-axle, B¹, is also clearly indicated in Fig. 1. The inner ends of the tie-rods are provided with small rollers, C², which engage with the cam-slots, D¹, and it is, of course, the curvature of these slots which provides the necessary correction of the previously-mentioned "errors."

A larger drawing of the cam-plate, D, is given in Fig. 2, and in this illustration the method of "setting-off" the curved slots is shown. Each cam-plate has to be designed for the particular car for which it is required, because the shape of the slots depends on the width of the track and the length of the wheel-base.

The neutral circle, a , is drawn to any convenient size on the cam-plate, and radial lines are drawn at angles of 5, 10, 15 degrees, &c., in each quadrant of the circle as shown. The centre lines, b , of the slots, D¹, pass through a series of points, situate on these radii, and the positions of the points are ascertained mathematically. The distances from the neutral circle of each point above the zero line is denoted in Fig. 2 by the letter, c , those below the zero by the letter, d . The lengths of these lines, c and d , are obtained by the following formulæ:—

angle, α , and also on the lengths of wheel-base and track of the car, its values being given by the following formula:—

$$\tan \beta = \frac{\text{wheel-base}}{\text{track} + \frac{\text{wheel-base}}{\tan \alpha}}$$

No account is taken in this formula of any effect which the distance of the wheel from the vertical centre line of the pivot, B (Fig. 1), about which it turns, may have on the amount of compensation necessary to correct the error.

From the practical point of view, the actual design of the mechanism shown in Fig. 1 has some obvious draw-

Fig. 2.—Klee's Tangential Steering Gear.—Detailed drawing of the cam-plate, D, showing how the cam-slots, D¹, are "set off" from the neutral circle.

backs which might militate against its success unless made with the greatest accuracy and with the most suitable materials. There are several places, for instance, where undue backlash would be likely to occur, and, of course, any such play would immediately neutralise the very advantages which the system is designed to give. It will be noticed, too, that the shape of the slots relatively to the fixed centre about which the

cam-plate turns, might in certain cases give trouble by being too pronounced in their curvature, and might make it difficult for them to operate the tie-rods, as also for the rods to keep steady in position when approaching the full-lock. Possibly the inherent weakness of any such system as this is the lack of any really positive mechanical connection between wheel and wheel.

LORD MONTAGU OF BEAULIEU.

THE Barony of Montagu of Beaulieu has, as the result of the death of the late peer, now devolved upon his only son who, as the Hon. John Scott Montagu, was so widely known as the champion of the automobile cause, and is universally so popular, especially in automobile circles. Everyone will sympathise with the new peer on his bereavement, and with the south of Hampshire on the loss which the district has suffered by the death of the late Baron. A younger son of the fifth Duke of Buccleuch, and raised to the peerage by Queen Victoria, he was conspicuous throughout his life in championing the rights of the people in the New Forest, and preserving many of the most beautiful and interesting portions of that great national demesne, when the Government Department, with characteristic short-sighted parsimony, proposed to deforest it. Progressive in all his tendencies, he was one of the earliest patrons of the A.C.G.B.I., and was throughout his life a continued supporter of mechanical traction in all its forms. The late Lord Montagu was a great traveller, and an intimate friend of the late Lord Salisbury and Lord Beaconsfield. The present Lord Montagu has done such yeoman service for the automobile cause in the House of Commons that it is scarcely likely he will be able to do more for it in the House of Lords, but his elevation to the peerage will certainly render him free from the anxieties of contested elections, and though he can but ill be spared from the ranks of the automobile Members of the House of Commons, he will prove a very great and valuable accession to the automobile interest as represented in the Upper Chamber, for above all he is a man of tremendous energy, and almost unequalled enthusiasm for the new locomotion, and there is little fear of his being overtaken by the lethargy which often overcomes previously active politicians when they enter the gilded chamber.

The Hon. John Scott Montagu, who by the death of Lord Montagu last week, succeeded to the title, is an apostle of the strenuous life. As one of the most energetic champions of the automobile cause, he has been a persistent and diplomatic fighter and an untiring worker.

ARMS FOR THE COUNTY COUNCIL.

PROPOSALS have been made that the County Council, as a corporate body, should assume a suitable coat of arms. It appears as yet not to have been decided whether the Council will devise arms for itself, or whether it will apply to the College of Arms for a grant. In the meantime our heraldic editor has been at work on the subject, and has devised what he ventures to think a very suitable coat, which he blazons as follows:—

Arms—Azure, a chevron, embattled, argent, between three steamboats, khaki, derelict and battered. On a chief, or, a bridge (uncrossed) between two tramcars, gules, stuffed and loaded.

Supporters—Dexter, an electrical contractor, handing out commissions. Sinister, a Ratepayer, depressed and seedy, both proper.

Motto—Dum micat sol colligo foenum. ("I make hay while the sun shines.")

Notification of Change of Address Necessary.—

Owing to the fact that his chauffeur one day last September happened to be driving his car through Battersea when the tail lamp had gone out, it was discovered that Mr. B. C. Cass had changed his address since the date on which he had registered his car, without giving notice to the local authority. He was accordingly summoned by the police on this count, and Mr. Marsham, sitting at Bow Street, before whom the case was heard on Tuesday last, decided that this constituted an offence, but as it was the first case of its kind he imposed a fine of only 10s., with 2s. costs. At the same time the magistrate said he was willing to state a case if that were desired. Mr. Amery Parkes, who, at the instance of the Automobile Association, took up the defence, appeared for the defendant.

MOTORING, SPORT AND TRAVEL.— THE VALUE OF THE AUTOMOBILE.

MOTORING, SPORT AND TRAVEL.

"WHILE proceeding towards Notre Dame du Lac Mr. Fitch saw a flock of partridges on the road ahead of him. Removing his gun from the hamper he shot several without leaving his seat behind the steering wheel." It is thus that one of the tourists on a big sporting expedition described how admirably a really up-to-date car can transport the enthusiastic stalker of game into the most out-of-the-way fastnesses. Sport is quite a different affair in the United States to what it is in this country. It is hardly possible for Englishmen to grasp how utterly isolated and apart from the stream of the world's affairs even many of the eastern parts of the United States are, and how little, in consequence, aboriginal wild life has been interfered with.

Not long ago, several prominent New York sportsmen determined to test how far the automobile could enable them conveniently to visit out-of-the-way districts, which to approach by other means would be, if not impracticable, at any rate extremely laborious, and they succeeded wonderfully. Mr. Ezra Fitch, who is a prominent member of most of the sportsmen's clubs of the Eastern States, organised and captained a sporting tour through the remote parts of Maine, and with him went Mr. Augustus Post, Mr. N. Lazarnick, Mr. A. T. Edmundson, and Mr. R. H. Johnson. The party knew they would have to traverse rough roads, and what rough roads are in the United States the European can scarcely realise. So they selected White steam cars as the most

MOTORING, SPORT AND TRAVEL.—A Canadian "Boulevard."

likely vehicles to successfully surmount the difficulties they knew they would encounter. Their confidence was rewarded, and never once throughout the most difficult and exacting country—mere woodland tracks which to compliment with the name of roads would be to outrage civilisation—were they ever left in a quandary. The three White touring cars were of the standard type, and only in one of them was the tonneau removed to accommodate the impedimenta of the exhibition, the hampers, canopy tops, and even the acetylene lights being retained. What the roads in the United States are, may be concluded from the fact that among these impedimenta were included "a road-building equipment," consisting of block and tackle, 400 ft. of strong ropes, four axes, a crow-bar, a shovel, and a mattock, and, besides these, a couple of extra springs and other parts were also carried, while, with a view to a life in the woods, there were aluminium cooking-pots, sauce-pans, plates and cups, a telescope stove-pipe, a rifle and fishing-rod for each member of the party, a quantity of ammunition, and any amount of fishing-tackle; while camping-out was provided for by a collection of air-beds and ground-clothes, each member of the party taking with him a heavy canvas kit-bag containing a sleeping outfit. The tourists shipped from New York to Portland, in Maine, where the tour proper commenced. From Oldtown the tourists ran along parallel to the Maine Central Railroad till they came to Mattawan-

kag, up to which, for America, the roads were fairly good. When this point was reached the tourists had some rather weird experiences of forest fires. A six weeks' drought had been in progress, and all the woods were like dry tinder. At one spot they encountered a place which had evidently been just vacated by a party of careless campers, who had not taken the trouble to thoroughly extinguish their fire, and the first stages of a forest conflagration were accordingly in full progress. Here the tourists spent fully an hour extinguishing the budding conflagration, and received a practical lesson in the extreme facility with which a forest fire propagates itself in dry weather, for though they apparently beat it out a dozen times, a dozen times it burst out again with renewed energy round the bole of some well-dried and hoary tree. Both on the same and the following day

a number of towns were passed which were just being completed, the new efforts in architecture being due to the fact that the former residences had all been wiped out by the forest fires of recent years. The towns and hamlets were deserted, for all the able-bodied inhabitants were out fighting the fires which were raging all round them. After passing a townlet rejoicing in the characteristic name of Braggville, the automobile sportsmen had experience of a forest fire at unpleasantly close quarters. Both sides of the road were burning, and whether they would get through or not was a very open question. However, after holding a council of war they decided to

MOTORING, SPORT AND TRAVEL.—One of the many difficulties experienced by the tourists. Clearing a forest road.

the border at Fort Kent, and, as owing to the drought, the river was unusually low, they successfully forded it on their cars, to the great astonishment of the inhabitants, who gathered on either bank to witness the extraordinary exploit. Opposite Fort Kent is the little Canadian town of Clair, and from thence they picked their way through Edmundston till they ultimately arrived at Notre Dame de Lac, where they were ferried across the Lake Temiscouata on an old-fashioned paddle-boat rejoicing in the appellation of the "Storm Hero."

It was near Notre Dame de Lac that Mr. Fitch secured several of the flock of partridges with his gun. The cars were got on board the steamboat without difficulty, but when they arrived at the other side of the lake the trouble began, for the boat could not succeed in approaching within some considerable distance of the shore. However, that was only a trifle to tourists

MOTORING, SPORT AND TRAVEL.—The value of the Automobile. Meal time.

make the attempt, and with a full head of steam successfully pushed their way through till they arrived at Patten in safety, nearly exhausted from the effects of the heavy smoke they had inhaled. The loftiest mountain in Maine—Mount Katahdin—was burning from top to bottom with the energy and abandon of a fifth of November bonfire, and the sight was one which the tourists will never forget, for they were fortunate enough to witness it during the darkness of the night.

With less danger and excitement they then traversed the high woods of Maine to such out of the way neighbourhoods that people positively asked the tourists if their cars were automobiles, and in the primeval forest at Masardis the whole party camped out for the first time, and were so delighted with their experiences over the camp fire that they all declared that "they had no further use for hotels or farmhouses." The really interesting experiences of the tour were to come, however. After leaving Masardis, the sportsmen-tourists continued their way in the direction of Portage Lake, beyond the camp at which spot their road lay through a dense forest, where they had frequently to chop away trees and branches, as shown in one of our illustrations, to get along, the difficulties being added to by the exceeding steepness or the gradients encountered. After passing the great belt of forest, they found themselves in a stretch of country in which English was an unknown language, this corner of Maine having been invaded many a year ago by French-Canadians, whom the belt of forest has completely separated from the outer world. Subsequently they crossed

who had come provided with a road-building equipment. In a very short time a rough pier was built up of logs and a gangway made along the top of it, and the automobiles run on shore. Here the party formed a camp far away from even the remotest indication of civilisation. The following day was spent in reconnoitring along the shore of the lake, and ultimately a "corduroy" road was discovered along which the steam cars laboriously made their way to Lake Touladi, where they camped and fished for several days, thoroughly enjoying the life of the wilderness.

When the tourists decided to return to Notre Dame du Lac, a scout was sent across the lake to fetch the

MOTORING, SPORT AND TRAVEL.—Two horseless carriages.

"Storm Hero" once more, after which they took the direction of the St. Lawrence River, reached the little town of St. Honoré, and passed through the province of Quebec.

The French-speaking portions of Canada through which they passed impressed the tourists particularly, as the architecture and style of the houses is quite different from anything encountered in English-speaking communities. Everywhere they were greeted with the greatest kindness and enthusiasm, though curiosity was truly rampant, the automobile practically penetrating these out-of-the-way corners of Canada for the first time.

Leaving the river near Bick, they ran through the woods, having occasion to construct extempore bridges, filling up holes with stumps of trees, and generally utilising their

MOTORING, SPORT AND TRAVEL.—A "pile" of logs.

negotiate the roads and transport the stores which the sportsmen took with them.

road-building equipment to the full. At one of their camping places during this part of the tour one of the sportsmen brought down a fine caribou which from a sportsman's point of view was regarded as forming "the climax of the tour."

The interesting result of the tour is that it really shows how valuable a car of the reliability of the White Steam car is in assisting sportsmen to get through the roughest country, at the same time carrying with them supplies and stores which it would be practically impossible to transport by any other means than the style of portage adopted in Central African expeditions. In fact, a whole battalion of carriers on foot would have been required to

MOTORING, SPORT AND TRAVEL.—The start of a forest fire.

"The Motor Academy."—Tuesday last saw the inauguration at Notting Hill of a new automobile teaching institution, "The Motor Academy," which occupies premises in Boundary Road, formerly used as a piano factory. The academy, which is especially designed for teaching the art of motor driving, is close to the Shepherd's Bush terminus of the Tube, and is accordingly readily accessible. The premises are well arranged for the purpose, being provided with a track of tarmac of 15 laps to the mile, surrounding a central expanse of asphalt on which side-slipping can be practised. All sorts of the usual artificial obstacles, comprising wooden terriers, and card-board chickens (doubtless that worse terror of the streets—the old lady with the umbrella—will be added in time), are provided to teach readiness in emergency to the pupils. In addi-

tion, the establishment includes a garage and lecture rooms. Mechanical repairing forms no part of the instruction. It purports to be a driving school especially designed for embryo amateur automobilists, though in future intending professional drivers will probably also be instructed.

MR. T. H. WOOLLEN, the honorary head timekeeper of the A.C.G.B.I., through his recent change to the control of the Clement-Talbot Works, has submitted this alteration in his position to the Races Committee of the A.C.G.B.I., and, under the circumstances, has offered to place his services at their disposal in an honorary advisory capacity. The Committee have, therefore, passed a resolution that a gold souvenir shall be given to Mr. Woollen as a memento of his period of office, with the best thanks of the Committee.

RACES, RECORDS, AND TRIALS.

THE 1906 TOURIST TROPHY REGULATIONS (SUBJECT TO REVISION).

THE provisional rules for 1906 have now been issued and are published below. It is possible the race may take place next year in May instead of September, in order to meet the wishes of the inhabitants and authorities.

General.

1. The Tourist Trophy shall be competed for between May 1st and October 1st in each year. The competition shall take the form of a race for touring cars, irrespective of country of origin, with a limited quantity of fuel, under the following conditions:—
2. The race shall be held under the Competition Rules for the time being of the club, in the United Kingdom or such other place as may be appointed by the club, and shall be organised by the club or by their nominees.
3. Cars may be entered by members of the club, of any recognised foreign or Colonial automobile club, or of any automobile club or organisation in the United Kingdom which is affiliated to the club.
4. The distance of the race, including controls, shall be not less than 150 and not more than 300 miles.
5. Cars will be required to stop and restart at certain points on the course.
6. The fuel to be used shall be provided by the club, and shall, for petrol cars, be petroleum spirit having a specific gravity of 0.695 to 0.705 at 60 degs. F. For 1906 the allowance of petroleum spirit for petrol cars shall be one gallon for every 25 miles, and of liquid fuel for steam cars one gallon for every 16½ miles, if the course be in the Isle of Man, and shall be an equivalent amount if the course be elsewhere.
7. The car completing the course in the shortest time shall be the winner, subject to compliance with these regulations, and the entrant of the car shall, on signing the bond and effecting the insurance required by the club, become holder of the Trophy.
8. No vehicle shall be driven in the race unless it conforms with the requirements herein contained.
9. The weight of the chassis shall not be less than 1,300 lbs. Accumulators and other ignition apparatus, the tyres on the wheels, the bonnet, tanks (empty), dashboard, steps, lamp brackets, and front mudguards, shall be treated as part of the chassis.
10. The load carried by the chassis, exclusive of fuel, oil and water, spare tyres, spare parts, luggage and provisions, shall be not less than 1,100 lbs., made up of:—
 - (1) The body with rear mudguards and their stays, floor boards and lamps;
 - (2) The driver and one passenger, with ballast (such ballast not to exceed 300 lbs.).
11. The chassis shall be in all respects of the ordinary touring type, and the car shall conform in all respects to the requirements of the British law. The chassis shall have not less than four road wheels. The distance between the centres of the wheels on each axle (*i.e.*, the track) shall not be less than 4 ft., and the distance between the centres of axles (*i.e.*, the wheel base) shall not be less than 7 ft. 6 ins. Efficient mudguards to the front wheels shall be fitted to the chassis. All tanks shall be fixed to the chassis and not to the body.
12. Efficient silencers must be fitted to all cars, and no form of exhaust release will be permitted.
13. The number of gears in the gear-box shall be restricted to not more than four speeds forward and reverse, except in the case of a variable speed-gear.
14. Every competing car shall be required to show that it is capable of being driven at 12 miles an hour on the level on the top forward gear and without the manipulation of the clutch.
15. Every competing car shall be required to show that it is capable of ascending a hill of 1 in 6 on the forward gear without a flying start.
16. The body shall be in all respects of the ordinary touring type, substantially constructed, properly upholstered and furnished, comfortably seated for driver and three passengers facing forwards, two in front side by side and two behind side by side, on seats at least 34 in. from the ground, with backs not less than 15 in. from the top of the cushions to the top of the back, and giving for every two seats not less than 40 in. in width between cushions. Efficient mudguards to rear wheels shall be fitted to the body. The platform behind the dashboard shall not be less than 7 ft. long, nor less than 30 in. wide, and the body shall cover this area.

The body of the car shall be easily removable by undoing not more than six bolts or hinges, and this removal of the body shall not entail disconnecting any part of the ignition apparatus, lubricating-pump connections, fuel-pipe work, or the fixings of any tank.

17. Between the start and finish of the race the driver and his mechanic only shall be permitted in any way to assist a car, and no stores, supplies (except water), spare parts or spare tyres other than those actually on the car at the start shall be taken on to the car during the race. Everything (except fuel) which is on the car at the start must be carried throughout the race.

18. No car will be allowed to start on the last round of the race within one and a half hours of the time at which the road will be opened to the public.

Entries.

19. Entries will be received by the club, at 119, Piccadilly, London, W., each year on the morning after the previous race. The holder of the trophy shall, unless he give written notice resigning the trophy, or unless he be not qualified for entering a car, be considered as having entered a car without a fee for the next race, in which he shall start first.
20. Not more than two cars by one manufacturer will be accepted. The club reserves the right to refuse any entry, and to limit the number of acceptances as circumstances may require. Subject to these provisos, entries which comply with these regulations will be accepted, and cars will be started, in order of receipt, provided always that the first entry of a manufacturer shall have priority over the entry of one of his cars by a private owner or by an agent.
21. The entrance fee shall be that which the club determines from year to year. (The fee for 1906 has been fixed at £20 per car). Entries at this fee will be received up to three calendar months before the advertised date of the race, after which the fee will increase by £2 per week up to one calendar month before the advertised date of the race, when the entries will finally close.
22. The entry fee will be returned in full if no race be held. When the entry has been accepted the entry fee will not otherwise be returnable.
23. Every entrant shall supply to the club, not later than the final date on which entries may be made, on a form to be provided by the club, a specification of the car or cars entered by him, and (if a manufacturer or dealer in motor cars) not later than seven days prior to the advertised date of the competition, a written undertaking to list and sell cars conforming in every respect with such specification until the advertised date of the next race.

Fuel Tanks and Connections.

24. Every car entered for the 1906 race shall be provided with fuel tanks of a capacity to be specified, which shall be made, fixed, and connected in accordance with the specification to be provided by the club.

Weighing and Examination.

25. The club shall appoint a place for weighing, and a day and hour prior to the race on which cars must be presented for weighing with their tanks empty. Cars shall be brought to and taken away from the weighing-station in such manner as shall be directed by the club.
26. Any loose ballast required by these regulations shall consist of canvas bags of sand containing not more than 50 lbs. each, and shall be provided by the competitor.
27. Every car which finishes the course shall thereupon be driven to the club enclosure under supervision with its full load, to be re-weighed, and fuel-tanks, water-tanks, and lubricating reservoirs shall be emptied by the club. If after the race the weight of chassis and weight of load carried respectively are found not to conform to the regulations, the car shall be disqualified. The club shall fix an hour after which no car will be received for re-weighing.
28. The club reserves the right to cut open any of the fuel-tanks, and to take such other steps as it may deem necessary to examine the fuel system of any car on the conclusion of the race. In any case, the fuel-tanks of the first three cars will be cut open on the conclusion of the race.

Road Regulations.

29. The driver need not be a member of an automobile club, but must be on the competitors' register of the club.
30. The driver and his mechanic shall be the only persons on the car during the race.

31. No competing vehicle shall be pushed or pulled over any part of the course under pain of disqualification.

32. No fuel capable of being used for the propulsion of the car in question shall be carried on the car, except the fuel provided by the club.

General Regulations.

33. In the case of a chassis or body which appears to depart from the ordinary touring type, the club reserves full powers to disqualify the vehicle.

34. A competitor by entering or by driving, thereby agrees that he is bound by the competition rules of the club and by the supplementary regulations herein contained or to be hereafter issued.

35. The interpretation of the regulations contained herein shall rest entirely with the club, which may at its discretion waive, alter, add to, or omit from, any or all of them from time to time.

If any dispute shall arise in connection with these regulations, or with the race, the decision of the club shall be final and binding, except in so far as is otherwise provided under the competition rules of the club.

36. The club reserves the right to postpone the race *sine die* if circumstances arise which, in its opinion, render such course desirable or necessary.

37. It is one of the conditions upon which entries are accepted by the club that the club shall not be responsible for any damage that may be done to the vehicle entered, or to its appurtenances, either during the race or while the vehicle is under the charge of the club, either by fire, accident, or otherwise, nor for the theft of the vehicle or any of its accessories or appurtenances. The vehicles and their accessories and appurtenances shall at all times be at the risk in all respects of the entrant, who shall be deemed by entering to indemnify the club against all proceedings, costs, and penalties whatsoever, relating to or arising out of the race.

38. If a competitor fails to comply with these regulations his vehicle shall be liable to disqualification.

39. A competitor by entering or by driving waives any right of action against the club for any damages sustained by him in consequence of any act or omission on the part of the club or of its servants or representatives with respect to these regulations, or to any matters arising therefrom.

THE Tourist Trophy Trophy for which, in the Isle of Man, so exciting a contest was run and won, concerning the corporeal whereabouts of which we recently made inquiries, is now about to materialise, and take actual, practical, tangible form. It is to consist of a silver replica of the Hermes at present in the South Kensington Museum, and is not to cost less than £250.

Motor Lifeboats.—The application of the motor to lifeboat propulsion is proceeding surely though perhaps somewhat slowly. A sub-committee of the National Lifeboat Institution, which had been appointed to consider the question, has advised that three more motors should be purchased and the Fishguard, Stronsay, Stromness, and Thurso Stations be provided with boats specially designed for the installation of internal combustion engines. Of the three motors above referred to, one is to be a 40-h.p. 4-cylinder Blake to be fitted to the Walton-on-Naze lifeboat, the second is a 24-h.p. Thornycroft to be applied to the Newhaven boat, and the third, a 4-cylinder 30-h.p. Britain, is for the Ramsgate self-righting boat. Reversing gear will be employed in each case, but reversible propellers will not be used.

The Iris Lubricator.—In describing the up-channel run of the "Iris" motor boat last week, we mentioned that Mr. Halliday, the enthusiastic navigator, was at one time compelled to sacrifice a bowl of nice hot turtle soup for the purpose of thawing his carburettor. This, as we are now informed by Mr. A. E. Perman, was a misunderstanding on our part, as the actual portion of the engine to which the fomentation of hot soup was applied was not the carburettor but the

ACRING under the resolution of the Automobile Club Committee that special awards be given to those cars competing in the Tourist Trophy race which are entirely of British manufacture, the Races Committee have resolved that only cars which completed the course shall be eligible for the special awards. The entrants of the 18 cars which completed the course have therefore been communicated with, for the purpose of ascertaining which of them claim awards on the ground of being entirely of British origin, and in cases of claims to submit evidence in substantiation thereof.

Voiturettes' Trials.—We were able last week to announce the route for these trials, taking place in Paris Nov. 21st to 27th, viz., from Paris (the Darracq Works at Suresnes) to Gaillon and back, on each of the six days' trials. The morning runs will also include a "circuit" of 30 kiloms. from Gaillon to Vironvay, making 115 kiloms. daily before luncheon, the afternoon run being direct back to Suresnes (85 kiloms.), daily total, 200 kiloms. In planning the route, it has been decided to avoid the severe Pecq Hill at Saint Germain, which at this time of the year is usually in a very bad state.

"Targa Florio."—This speed race to be held in Sicily in April or May next promises to develop into an event of considerable importance. Signor Figari has promised 30,000 francs for prizes, to which Cavaliere Florio has added 20,000 francs. The proposal is for the start to be made on the absolutely straight 6-kiloms. strip of level road skirting the sea coast from Palermo to Cefalu, and the circuit will probably be so arranged as to eliminate as far as possible all railway level crossings.

BARON DE CATERS has offered through the Academie des Sports a cup, value 5,000 francs, for competition for accessibility in all the parts of a motor. The competition is to take place and be decided during the first eight days of the Paris Salon in order that the successful manufacturers may reap the fullest benefit during the Salon of any reward which they may obtain.

lubricator in which, owing to the exceptionally low temperature encountered, the lubricating oil had congealed.

British Motor Boat Club.—The First Annual Dinner of the British Motor Boat Club will be held at the Hotel Cecil on Friday, December 1st, at which the Commodore of the Club, Admiral Sir William Kennedy, K.C.B., will preside. There will be, subsequently, an entertainment of a novel character.

MOTOR CYCLING.

THE annual dinner of the Auto Cycle Club is to take place at the Criterion Restaurant on January 17th.

THE first 100 miles trial for motor cycles under the auspices of the Auto Cycle Club is to take place about the end of January.

3½ H.P. motor cycles for 25 guineas are promised by the Rex Motor Manufacturing Company for 1906, it being affirmed by the company that these are in no way inferior to the 50-guinea machines.

THE ½rd Litre Motor Bicycle Competition at Marseilles resulted, in the final on Sunday last, in a victory for Thomas on an Alcyon machine (Dunlop tyres) with the time of 1h. 22m. 53½s. for the 100 kiloms. Capeaumont, on a Lurquin-Coudert, was 27 laps behind, Giuppone (Peugeot), 30 laps, and Colin (Magali) 32 laps.

Very few ruling monarchs of Europe are now without automobiles in, practically, daily use. One of the most enthusiastic of Royal Automobilists is King Alfonso of Spain, who usually also drives his car himself. Upon the recent visit of President Loubet of France to Spain, King Alfonso personally drove the President upon several occasions during his visit. Our photograph is a memento of one of these runs, when King Alfonso is seen at the wheel of his car with President Loubet seated in the tonneau.

Sirens and Exhaust Whistles to be Tabooed, and the "Motoring School" Question.—We are glad to see that the Motor Union, at its last meeting, unanimously agreed "that steps be taken to discourage the use of sirens and exhaust whistles in towns and populous districts." This is an excellent resolution as far as it goes, and we hope the Union will act upon it with its customary determination. The only thing we regret about it is the limitation. Both the siren and the exhaust whistle, but particularly the siren, emit howls of such a furiously exasperating character, that even in the centre of the Sahara they might be confidently relied upon to raise up an army of anti-automobilists. In respect to the use of hooters, we are glad to notice that there is a general feeling growing in favour of prohibiting the use of horns by the "boulder" cyclist, a point we have, in and out of season, advocated. Let cyclists use bells, as was their wont, and restrict the use of the horn to mechanically-propelled vehicles.

At the same meeting of the Motor Union very caustic remarks were made in regard to so-called schools for teaching motor car driving. It was (very wisely) suggested that the Automobile Club and Motor Union should jointly go into the question, and if possible determine how the matter should be dealt with in view of the unsatisfactory character of the existing automobile schools.

Civic Amenities.—When the London County Council decided to electrify the South London tramways, the *Daily Mail* criticised the policy of which this was the

outcome, and declared that the cost would be higher than the estimates, and that the estimates did not fairly disclose what the tramways were expected to cost. The same paper also pointed out that the coming of the motor 'bus would have a very serious effect upon the future of the electric tram earnings, and since that time it has occasionally criticised the policy of the County Council in regard to its very questionable speculation in maintaining a service of steamboats on the Thames. This and other allied subjects came up for discussion at the meeting on Tuesday last, when Mr. Burns, who has for some occult reason been the protagonist of the electric tram and steamboat policy of the Council, is reported to have expressed himself as follows:—

"Were they to be bullied out of their duty to the people of London simply because a paper owned by blackguards and edited by ruffians attempted to intimidate them?" (Cries of "Withdraw").

There are some people whose abuse is more flattering than the highest compliments they could pay, and we do not think we are misinterpreting the views of Sir Alfred Harmsworth if we conclude that he will regard this testimonial as one of the most satisfactory that in his distinguished career he has ever received.

A LECTURE was delivered on the 23rd ultimo at the Nottinghamshire A.C. by Professor Robinson, the Principal of the Engineering Department of the Nottingham University College, on "Motor Car Engines." The lecture was illustrated by actual working models and also by lantern slides.

CORRESPONDENCE.

CO-OPERATE FOR MUTUAL PROTECTION.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—It is, as you know, the aim of the Automobile Association to extend its system of Cyclist Patrols to every highway in the kingdom. At first sight, this may appear Utopian, but it is not. Take the case of the services. In garrison and harbour towns it is an unwritten law that the civil authorities shall studiously avoid conflict with soldiers and sailors on leave in all matters of trivial importance, leaving Jack or Tom to the expert treatment of his comrades in the picket. My simile may be far-fetched, but I hold that speed on open country roads, being a matter of trivial importance so far as the safety of the public is concerned, it may and should be left to the no less expert treatment of trained patrols such as our organisation can establish.

Let like manage like; the method has obtained for hundreds of years in the services and it works well there. It will work even better with motoring.

An efficient system of automobile police—and we have it in embryo even now—can protect the public from the motorist and the motorist from himself. At an average cost of 2d. per mile per day, bicycles included, intelligent and conscientious men can be provided, each of whom will protect a beat varying from five to ten miles, every point and turn of which he knows by heart.

Hidden and moving dangers such as herds of cows, flocks of sheep, caravans, &c., from which the thoughtfully-placed triangle of the A.C.G.B.I. cannot always be hoped to save a driver, will be located by this wheeling policeman with advantage to all concerned. The Road Hog, abhorred as he justly is by all and loathed especially because of the social mud he scatters over his fellow drivers, will soon become extinct under the new *regime* by reason of the fact that, go where he will, his actions will be watched and checked by a controlling medium, the more implacable because it is unbiassed, the more conscientious because it is uninfluenced by profit. As the matter stands at present, the scorching fiend fears only the annoyance of a police court fine, and even this is mitigated by reflections upon the "prejudice against automobilism" which he shares equally with his gentler brethren. But let him incur uncompromising repression, let him feel that all the prejudice and all the odium is against him alone, and he will shiver in isolation, and the scorching bacillus will die.

Intelligent organisation can bring this about; therefore, let us weed our own garden. It is cheaper and far more dignified than allowing it to be done by county magistrates who may be quite competent, but certainly have no pretence to expert knowledge. Twopence per mile per day is no more than the tyre wear of one powerful car. A thousand miles of glorious open road can have efficient protection on every day in the year for two guineas per annum from fifteen hundred members, and the greater area covered the less proportionate cost.

The necessity for grasping these facts cannot be too strongly urged upon automobilists. Compared merely with the inconvenience and annoyance caused by untimely collisions with the authorities, and leaving out the matter of "financial consequences," a subscription of two guineas is almost infinitesimal.

As I have said, the scheme is not Utopian, neither is it impracticable. Let it only be borne in upon every motorist that he can no more expect to drive in districts guarded by automobile police at all but at his own expense, than he would for ever ride free on his friend's car, and the irritating regulations as to speed in safe open country can soon be rendered unnecessary.

The tradespeople, the local police, and the public generally will also benefit materially, and by virtue of this a better and proper understanding will be brought about.

Surely one *entente cordiale* is worth forty treaties.

I am, sir,

Your obedient servant,

STENSON COOKE.

Secretary, The Automobile Association,
18, Fleet Street, E.C., Nov. 3rd, 1905.

POLICE PROTECTION AND "POLICE TRAPS."

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In your last issue you quote some remarks which I am supposed to have made, presumably, in reference to the burglary that was recently attempted at my house at Cobham. Will you allow me to say that I have made no statement whatever on the subject, and that the whole affair has been grossly exaggerated in

the newspapers. I certainly think the police would be better employed in their normal duties during the daytime than in setting traps on open roads; but I have every reason to believe that the night patrolling is done in an efficient and conscientious manner, considering the smallness of the local force, and the scattered nature of the district.

I am,

Yours faithfully,

F. P. ARMSTRONG.

Cobham.

⊗ ⊗ ⊗ ⊗

Triumphs of the Motor 'Bus.—Our readers are aware that 'buses belonging to the London Motor Omnibus Company have been successfully running from London to Brighton since August 30th last. The experiences have been so satisfactory that the Company has now decided to organise a regular daily winter service, and a motor 'bus will accordingly start from Northumberland Avenue every morning at 9 o'clock, returning at 9 p.m. the same day. During the winter, the tops of the 'buses are to be entirely dedicated to the transport of goods and baggage, and passengers will be confined to the inside, which will be carefully heated. 40 lbs. of luggage will be allowed free to each passenger, and the 'bus company also hopes to develop a goods service between intermediate towns and villages, as parcels weighing up to 28 lbs. will be received and conveyed to their destination for 6d. Regular stopping-places will be at Croydon, Redhill, and Crawley, though, of course, passengers can book to or from intermediate places. At present, as the speed of vehicles of the size of the motor 'bus is limited to twelve miles an hour, the journey takes four and a half hours, but should relief be afforded in regard to the speed question in the near future, as is confidently anticipated, the 'buses would be very well able to perform the journey under three hours. It is anticipated that three hundred of these 'buses will be in use before the end of next year, though of course this number will be distributed over all the Company's other routes. The motor 'bus is certainly going to be the vehicle of the future, for holidays, outings, beanfeasts, and other junketings, as it can now be hired by the day either in summer or winter. Next year it is probable that we shall see other country road services in full operation. Already the Company have successfully handled large parties for long distance journeys, taking excursions to Torquay and other seaside places, and returning to town at prearranged times. By the further developments foreshadowed in the same direction, there appears to be no limit to the ultimate usefulness which the motor 'bus and large motor cars may ultimately be shown to possess.

Glasgow Motor Car Show.—Particulars have been issued of the Exhibition which is to be held in Glasgow at the Exhibition Hall, Duke Street, from March 9th to 17th next. This hall is the largest exhibition building in Scotland, and the exhibition will be under the general management of Mr. Walter Cawood, Mr. J. Pownall-Goodhall being the secretary, with offices at 37, West George Street, Glasgow. A splendid list of honorary patrons, headed by the Duke of Argyll, is announced on the prospectus, the Honorary President being the Lord Provost of Glasgow, Sir John Ure Primrose, Bart., and the Hon. Vice-Presidents, Messrs. W. Alexr. Smith, J. R. Nesbit, and J. R. Chalmers. Under Mr. Cawood's management the exhibition should prove a big success.

TURIN Automobile Salon is announced to be held from February 3rd to 18th next.

Napier Major has during the past year had a busy season on the water, covering 8,000 miles in her travels. She was the chief object in a new form of trip last week, when she was transported by land, as seen in our photograph, from Messrs. Yarrow's works at Poplar to Messrs. S. F. Edge's Marine Stand at Olympia, where she is now having the finishing touches put to her "toilet" in anticipation of the admiring gaze of the visitors to the Olympia Show.

Olympia Motor Show.—Amongst those who have promised to be present on the invitation of the Society of Motor Manufacturers and Traders at the opening function of the Olympia Motor Exhibition on Nov. 17th are the following:—Hon. A. Stanley, M.P., Right Hon. H. A. Arnold-Forster, M.P., Right Hon. Sir John Macdonald, Sir David Salomons, Major J. Eustace Jameson, M.P., Sir Thomas Lipton, Sir Boverton Redwood, Mr. J. Bull, M.P., Sir Ernest Clarke, and Colonel Holden.

MEMBERS of the Motor Union will be admitted free to the Olympia Exhibition on Wednesday, the 22nd November, on presentation of their cards of membership for the year 1905 or for 1906. The Union will have a stand at the Show (No. 8a, close to the Prince's Rooms), where members may obtain any information, and at which non-members may be enrolled.

As a very large number of cars will be in use giving trial runs during the Show, a timely caution has been issued by the Exhibition authorities, drawing attention to the necessity for precaution in order that no complaints shall be occasioned in the locality by reason of reckless or negligent driving or discourtesy on the part of drivers. In view of the position at the present time this is a most important matter, and exhibitors are therefore requested to place these cars in the charge of their most careful drivers with such explicit instructions as will prevent any complaints arising in this connection.

THE Fire Office and London County Council rules prohibit absolutely the storage of any petrol inside Olympia whether in cars or otherwise. Consequently, petrol cars for exhibit going down by road must be *completely emptied of motor spirit* before entering the building.

On the last occasion several drivers, although informed that their petrol tanks and carburettors must be first emptied, attempted to force their way past and drive into the building, and in some cases succeeded in doing so. On this occasion it is probable that the authorities will be more strict as to the least infringement of this regulation.

EXCURSIONS from all parts of the country are being organised to London to enable visitors throughout the United Kingdom to visit the Olympia Show on November 17th to 25th.

Alcohol and Paraffin for Industrial Motors.—Mr. Dan. Albone has recently been conducting experiments with alcohol and paraffin for ploughing purposes. For this purpose special attachments were constructed for use with the Ivel motor, which was not, in itself, altered in any respect. As the results of three tests carried out with the same machine, on the same soil, and during the same day, Mr. Albone found that with 2 gallons of petrol he could plough 3 roods of land, while with the same quantity of paraffin and alcohol only 2 roods 35 poles and 2 roods 25 poles were ploughed, respectively.

Brighton to Edinburgh on Top Gear.—The famous great North Road seems likely to become a regular *pons asinorum* to the motor world, and the Belsize Company have already undertaken to negotiate the same by offering to give any purchaser of one of their 6-cylinder cars a "top-gear" run from Brighton to Edinburgh as a trial trip; in the event of failure to maintain "top gear" throughout, the purchaser to have the option of crying the deal "off."

SOME time ago, when the London County Council were promoting their Bill to bring their trams over the Thames bridges, it was decided that a *sine qua non* was that Blackfriars Bridge should be widened. The Court of Common Council, with the Lord Mayor presiding, have now decided to promote a Bill to empower them to widen the bridge to an extent not exceeding forty feet, provision also being made for curving off the bridge properly as it runs on to the Embankment. An important provision that will be enforced is that the trams when they are brought over the bridge (if they ever are) shall not stop on the bridge, nor within twenty-five yards of the ends thereof, and that the County Council shall pay an annual rent for the use of the bridge for their trams.

ON Friday of last week a dinner was given by Messrs. C. S. Rolls and Co. to Mr. Percy Northey and Mr. F. W. Royce, the amateur driver and the manufacturer respectively of the Rolls-Royce car, which secured second place in the recent Tourist Trophy Race. The Hon. C. S. Rolls occupied the chair, and the occasion was marked by several quaint little automobile conceits introduced into the surroundings of the dinner, a presentation to the two guests of the evening, and the promised unravelling of the mystery surrounding the new landaulette which the firm have determined to put on the market for 1906. The latter was, in many respects, an interesting announcement, and the particulars of this new departure in the design of the Rolls-Royce car will be found in detail in another part of the journal this week.

The other "events" of the evening were a cleverly designed menu card in the form of a full-grown motor car, the top of the canopy of which served for the menu, a goggle mask on which was indicated the seat of each guest, a mammoth ice motor car, fully illuminated, and last, but not least, the presentation to Mr. Northey and Mr. Royce of two large silver cigar boxes and two enlarged photographs of Mr. Northey in "war paint" on the successful Trophy car—altogether a pleasant little series of episodes. Startling and mysterious was the bringing in, immediately after nature's requirements had been satisfied, of two closely-veiled easels, which proceedings were followed by the assembled company with keen curiosity, mixed with just a touch of hushed awe, at the thought of what might be in store for them. These, however, turned out subsequently to be, at the wave of the magician in the chair, no more fearsome than the aforementioned presentation photographs.

Mr. Royce, in response to the praise of Mr. Rolls for having produced so fine a car as the Rolls-Royce, modestly protested that all he had done was to put a few pieces of metal together for Mr. Northey to risk his neck upon. Mr. Northey was equally emphatic in reply in putting the blame on Mr. Royce for his having done so well in the race. Said Mr. Northey, it was the most monotonous drive he ever had—he simply pressed the button, and Mr. Royce did the rest. The fact that he, an amateur, had been able at a moment's notice to drive the car through a non-stop run, was due to the excellence of the work put in by Mr. Royce, his skill in driving being merely an item in the scheme. And so with the toasts of "The Press," by Mr. Claude Johnson, and "The Guests," by Mr. Rolls, concluded well before 11 o'clock, a very enjoyable function, remarkable for its short and pithy speeches, and various delicacies dis-

guised by the *chef* under names appropriate to the occasion, of which the following effort was the most noticeable: *Supreme de sole à l'Épingle à Chevaux*.

MR. STEPHEN COLERIDGE has been having some more fun at the expense of the great unpaid and the police. He was recently summoned to appear before the Brentford magistrates, but, being unable to attend, sent the following letter by his chauffeur, which the latter read out in open court:—

On the 13th of October, towards nightfall, I was proceeding in my automobile along a lonely stretch of road in the neighbourhood of Norwood, when I was stopped by three highwaymen, who sprang out of the hedge, where they had been lurking.

They were armed with stop-watches, and I had no weapons or defence, and no means of refuting anything they might say or do then or to-morrow. The gentlemen of the road performed their violent interruption of my peaceable journey with the gay courtesy of their classic forerunners, and we quite expected P.C. Richard Turpin and P.C. Claud Duval to insist on the ladies of my party descending to tread a measure with them in the mud.

I am told that the roads round Andover have become so dangerous to travellers in automobiles that the town is practically deserted, and the inhabitants are taking serious steps to clear the road of these footpads and restore the traffic.

Perhaps at Brentford, however, there are some enterprising inhabitants who are glad to be quit of these dangerous characters, who now spend the livelong day in ditches by lonely roads watching for defenceless tourists.

The reading of this letter was at once followed by a conviction, the magistrates telling the chauffeur to inform his master that he would be subjected to the full penalty of £10, the case being merely formally adjourned in order that previous convictions might be proved against him. It is perhaps well for Mr. Coleridge that it was not the Steyning Bench before which he was summoned, as in that case, probably after the reading of his letter, a warrant would have been issued for his arrest.

APROPOS of the recent inquest held by the City Coroner, Dr. Waldo, into the Cornhill lorry fire, our attention has been drawn to the importance in such technical cases of adequate provision for the calling and examination of expert evidence being provided in future. The Coroner's Court has no machinery for dealing with what may be termed "technical fires," that is to say, fires in which the evidence in regard to their origin is likely to be of a highly technical character. With the growth of industrial development, it is obvious that the need for this want being supplied becomes more and more pressing.

THE police are not always, it seems, as amenable to the wishes of the authorities who are supposed to, or should control them, as is supposed. Only when these authorities are thoroughly reactionary do the police appear to work in perfect harmony with them. This, at least, is the conclusion which is naturally to be drawn from the situation prevailing in Lancashire. The chairman of the Main Roads Committee of the Lancashire County Council, at a recent meeting, referring to motor traps, said he had expressed a strong opinion to the Chief Constable that police supervision of the road should be concentrated on villages where human life is likely to be endangered, instead of setting traps on isolated stretches of road. The annunciation of this sentiment evoked loud applause, but the Chief Constable, it was stated, had replied that while the speed limit was in force he could not neglect it, but, at the same time, he would in future pay more attention to the frequented and populous parts. Let us hope, therefore, that he will not have sufficient police available for both.

The unique motor car menu card and guests' mask which formed one of the little surprises at the Rolls-Royce dinner last week. The top of the canopy of the car formed the menu.

A J

One of the latest cars of the Germain Company is seen in our photo above. It is a 24-32-h.p. Tonneau Royal with cape-cart hood. This carriage is particularly well designed and is a striking example of a luxurious vehicle. A supplementary seat is supplied for the chauffeur, over the tool-box and the trunk holder, at the back of the carriage.

A St. Neots Gem.—There may be ingenuous individuals who believe that the things automobilists and the automobile Press say about police evidence are exaggerated. Many people have been brought up to believe that the constable, village or other, is a blue-coated embodiment of absolute truth. It is a poetic conception, but like many other poetic conceptions, it is but remotely connected with facts as will be admitted by all who have experience of proceedings at the notorious St. Neots Police Court. Within the region over which that august tribunal exercises its Rhadamanthine sway is situated—in the village of Buckden—a police trap, or if we adopt the most recent nomenclature, a motor car trap manned by policemen.

Through this contrivance recently proceeded the automobile of Mr. J. B. Allpass. The chauffeur was alleged to have driven to the public danger, and to have refrained from stopping when a policeman held up his hand for the purpose of inducing him to do so, though apparently the summons which was served upon him only mentioned the latter offence. There was little traffic at the time, the whole of it consisting of one

wagonette, three cyclists, two women, and some men. As evidence of the dangerous manner in which the motor car was driven, the coachman of the wagonette was produced, who declared on oath that the car passed only 10 ins. from him. The police subsequently swore that they had examined the wheel tracks of the wagonette and the motor car, and measured the distance between them on the road, and that the distance between the wheel tracks was exactly 10 ins. This was most remarkable, for the automobile was provided with dust-guards extending a full foot on either side of the wheels, and the axle-box of the wagonette also extended ten inches on either side of its wheels. If, then, the police declaration (on oath) were the absolute

undiluted truth, either the wagonette ought to have carried away about twelve inches of the motor car, or the motor car have removed about ten inches from the wagonette. Neither of these phenomena are mentioned, however, and we are reluctantly forced, therefore, to the conclusion that the police have, in a manner not altogether unusual in the force, been *economising* the truth. No clear signs, it would seem, as required by the Act, were made by the policeman, and when the occupants of the car passed him, they merely thought he was jumping about, either for the purpose of relieving his feelings, or with a view to inducing circulation. At any rate, he never distinctly held up his hand. Though all these points were brought out in evidence, and enforced in a lengthy and eloquent speech by the solicitor for the defendant, the Bench (as might have been expected by those familiar with St. Neots) fined the unfortunate chauffeur £8 on the one count and £4 on the other. Mr. Clark, solicitor for the defendant, vainly appealed to Quarter Sessions precedents to show that where danger to the public is alleged, such danger must be proved. The St. Neots magistrates were far above considerations of that kind, and said that they were not bound by Quarter

Considering that the Tyres shown in the above photographs have already run a distance of 3,445 miles throughout England and Scotland, it will be noticed that they show practically no signs of wear. Not only does this speak remarkably well for the tyres which are now being turned out by the Dunlop Company, but, as Mr. S. F. Edge justly contends, it is a convincing proof of the good all-round design of the car using them. The dimensions of the tyres are 810 and 90 mm., while the car, which is one of the new 18-h.p. "Regents," weighs about 19 cwt. without passengers.

The London and North-Western Railway Company last month commenced running a service of motor omnibuses, one of which is seen in our photo, between Holywell Station and Holywell Town, North Wales. The town, $1\frac{1}{2}$ miles distant, is on the side of Halkyn Mountain, 550 feet above the railway station, so that the motor omnibuses have some heavy collar work, parts of the road being as steep as 1 in 9. The experiment is proving very popular, as the 'buses are nearly 15 minutes quicker than the horse vehicles hitherto plying between the same points. The new service is expected to bring a great many visitors and pilgrims to St. Winifred's Well, which has been noted for over twelve hundred years for its healing properties. The omnibuses meet every train at the station, and make 18 journeys daily to the town and back.

Sessions decisions. Alas, they are not, or by anything else, apparently, but their miserable contempt for fair play and the elementary principles of justice. When the case was practically over, the Chairman of the Bench recalled a policeman, and asked him the following questions:—

"Were you stationed at your usual place?"—

"Yes, sir."

"Did you make the usual signal to stop?"—

"Yes, sir."

"Is there any difference between this case and the others you bring before us?"—"No, sir."

If, in addition to all this, it were true, as we are at present advised, that the defendant was only summoned on *one* count, but convicted and fined on two, the situation amounts to a very grave judicial scandal.

One cannot help calling to mind a story of the earlier days of the "great unpaid" before the motor car had come to muddle the contents of their crania. It was at a Derbyshire Petty Sessions Court. A rustic had been proved to have committed the grossest cruelty to a dog by sticking him through and through repeatedly with a pitchfork. When the whole case was over and it was expected that the magistrates would give their decision, the chairman, who was very much against the dog, recalled one of the witnesses and solemnly asked him, "Do you think this treatment *really* hurt the animal?"

MESSRS. LEGROS AND KNOWLES, LIMITED, are not only thorough in their engineering undertakings, as witness the cars which they have already marketed, but are equally pre-eminently "at home" when dispensing hospitality to their many business friends. A delightful evening was arranged last week at the Hotel Cecil, when the new features of the Company's cars for 1906 were fully explained and illustrated. In addition to the valuable experience and skill of Mr. L. A. Legros and Mr. G. J. F. Knowles, the firm have with them another mainstay in Mr. I. de Havilland, who has been associated with the Daimler Motor Company as designer. It was news to many of the uninitiated that the firm are well forward in the manufacture of an "all-British" motor 'bus chassis, which, like the rest of their "confections" has been undergoing every possible test and trial, so that it shall not be found "wanting," before being placed on the market. A goodly company was keen in appreciating the many excellent points of the cars, all of which are dealt with by us in a special article which appears in the current issue. The speeches, for the most part, were short and witty, whilst a well chosen little band of entertainers, between speeches, made the time pass too rapidly, and the evening all too short. Mr. A. E. Perman, as

one of the vice-chairmen, was throughout watchful that the enjoyment of the firm's guests never flagged. A very practical innovation was placing one of the new engines and the gear-box on view in the reception room for inspection.

In our issue of October 14th, we announced the important move which was being made by the Sirdar Rubber Company in securing large mills at Bradford-on-Avon. We are this week able to give the above photo of this new acquisition. The mills are freehold and cover over six acres of land. The Company's old mills are still working day and night, and although they have been built on to, they are unable, we learn, to supply the demands for the Company's tyres.

BIRMINGHAM Motor Exhibition for 1906 will again be held at Bingley Hall from January 19th to 27th, Mr. Walter Cawood again being responsible for the general managership. We understand that already a number of important manufacturers of British and foreign cars have secured places.

THE motor omnibus service which is running between Haslemere and Farnham should be a "boon and a blessing" to golfers who make the new links at Hindhead, opened by that good motorist, Sir Arthur Conan Doyle, last week, their particular haunt, as these omnibuses pass the door of the club house.

IN a novel form a series of very interesting articles on tyres are appearing in *The Times* each week. The first three appeared on October 20th, 27th, and November 3rd respectively. The Michelin Tyre Company are responsible for this series, in which many historical facts and practical data are brought out, recalling pleasant memories of the past.

MR. W. M. LETTS, who has just arrived back from the "States," reports having put through, in connection with the De Dietrich firm, the second biggest deal in automobiles in the United States. Things automobile in America, he thinks, look healthier than they ever did before, and the good work done by the National Association of Automobile Manufacturers is having an excellent effect.

BRITISH EXPORTS AND IMPORTS OF MOTOR CARS, &c., FOR 1905.

NOTE.—For 1904 comparative figures see full table for the year in our issue for January 21st, page 91.

COMPANY DOINGS.

Daimler Motor Company (1904), Limited.—The directors, in their report for the year ended September 30th, state that the net profit for the year, after provision has been made for debenture interest, depreciations, and all charges, amounts to £83,167. Deducting interim dividend on 64,200 preference shares (10s. paid) at the rate of 6 per cent. per annum (£963), there remains a disposable balance of £82,204. Out of this balance the directors propose to write off preliminary expenses £1,257, to transfer to reserve £30,000, to pay a balance dividend of £963 on the preference shares, and a dividend of 6 per cent. on the ordinary shares (£3,736), free of income-tax, and to divide the surplus available for dividend equally between the shareholders as provided in the articles of association (£4,982), carrying forward a balance of £41,264. With the approval of the shareholders, a reconstruction scheme was carried out in the autumn of 1904, and a new company, called the Daimler Motor Company (1904), Limited, was registered on November 19th, 1904, with a capital of 100,000 ordinary shares of £1 each and 100,000 6 per cent. cumulative preference shares of £1 each. The debenture stock (£60,000) issued by the old company was taken over by this company.

The shareholders of the old company received 62,269 fully paid ordinary £1 shares in the new company.

Out of an issue of 75,000 preference shares, 64,200 were subscribed for, and 10s. per share has been called up.

In September, 1905, the negotiations which had been going on for some time with the Motor Manufacturing Company were brought to a conclusion. All the leases held by that company were surrendered, and this company reacquired the buildings and land which were in 1897 sold by the Daimler Motor Company to the Great Horseless Carriage Company, the predecessors of the Motor Manufacturing Company. This company at the same time purchased the greater part of the plant and machinery belonging to the Motor Manufacturing Company. The debenture stock has been reduced from £60,000 to £49,800 by the purchase of £10,200 stock, which has been handed to the trustees for the debenture-holders and cancelled. The exceptional success of the company's cars during the past season has, state the directors, fully proved their excellence and superiority, and has largely contributed to the great increase in orders and sales and the satisfactory results shown in the balance sheet.

Humber, Limited.—The profit of Humber, Limited, for the year ended 31st August, amounts to £6,537, and £3,334 was brought forward. There is an available balance of £9,872. The directors state that the cycle sales have largely increased, and that profits show a marked improvement. The motor trade has also been good, and the directors regard the future very hopefully.

AMONGST recent purchasers of Simms-Welbeck cars is Lord Glerawly, who has lately become the owner of one of the handsome 20-24-h.p. cars made by the Simms Manufacturing Company.

CONTRARY to the original intention of the Continental Tyre Company, they have now decided not to hold a tyre-fitting competition at the Olympia Motor Show. They anticipate a very large number of visitors at their stand, and consider that the holding of this competition might interfere with the course of business.

1905.	Exports, British and Irish make.				Foreign and Colonial Re-exportation.

NEW COMPANIES REGISTERED.

[Taking powers to manufacture or deal in motors, motor cars, or accessories, either as their principal or part of their objects.]

British Empire Motor Trades Alliance (Limited).—Registered, with 250 members, each liable for £1 in the event of winding up. The management is vested in a committee.

British Motor 'Bus Trust (Limited).—Capital, £105,000 in 100,000 "A" shares of £1 each and 100,000 "B" shares of 1s. each.

Cremorne Motors (Limited), Cremorne Motor Works, Lots Road, Chelsea, S.W.—Capital, £30,000 in £5 shares (2,000 six per cent. cumulative preference). Object, to acquire the business carried on by A. E. Dobbs, at the Cremorne Motor Works, Lots Road, Chelsea, as the Cremorne Motor Manufacturing Company. First directors: A. E. Dobbs, W. East, J.P., and A. F. Dobbs.

Fitzgerald Tyre Syndicate (Limited), 192, Goldhawk Road, W.—Capital, £10,000 in £1 shares. Object, to acquire the patents for a pneumatic tyre for motor vehicles, &c. First directors, J. H. Fitzgerald (permanent), P. B. Marshall, and F. Humphries.

P.M. Electric Manufacturing Company (Limited).—Capital, £2,000 in £1 shares. Object, to carry on the business of manufacturers of electrical apparatus, sparking plugs, induction coils, &c. First director: P. Baxter (permanent).

R. Reynold

13, High Street,
(4,900 "A" and
on at Notting H
mechanical engineers, manufacturers of and dealers in motor cars.

The Glasgow Motor Tyre Company (Limited).—Capital, £2,500 in £1 shares. Object, to acquire and carry on the business of the Glasgow Motor Tyre Company, 71, Waterloo Street, Glasgow. (Scotch company).

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

22059. 13th October, 1904. Improvements in Oil and Spirit Explosion Engines. Frederic Bamford, 97, Shaw Heath, Stockport, Cheshire. This invention relates to oil and spirit engines of the two-stroke cycle type. There are four figures. Fig. 1 is a sectional elevation; *a* is the engine cylinder provided round its upper part with a water jacket, *b*. An annular chamber, *c*, is provided round the lower part of the cylinder, and this annular chamber communicates at one point, *d*, with the crank chamber, *e*. The connecting rod, *m*, is made hollow and of considerable size, and it connects the piston, *n*, with the crank pin, *o*. The carburettor, *p*, is connected to the annular chamber, *c*, by a pipe, *q*, on which is placed a non-return valve, *r*. During the upward or inward stroke of the piston air and fuel are drawn from the carburettor or vapourised into the annular chamber, *c*, and through this chamber into the crank chamber, *e*. At the same time additional air is drawn past the valve, *s*, provided on the pipe, *t*, into the top of the annular chamber, *c*, on the other side

projection or directing plate, *x*, is formed on the top of the piston, so as to direct the entering fluid upwards, and reduce the amount of mixing between this entering fluid and the products of combustion from the last explosion. The air and fuel get heated in the annular chamber, *c*, most of the charge passing through this chamber twice, and the mixing of the petrol is made more complete than it would otherwise be. An advantage of this arrangement is that when desired a weaker charge can be fired in the cylinder than would otherwise be possible, owing to the mixture at the instant of ignition being comparatively rich at the top end of the cylinder and comparatively poor at the bottom end of the cylinder. This is due to the fact that almost pure air enters the cylinder first, sweeps up to the top of the cylinder, and is then displaced to the bottom of the cylinder by the succeeding fluid which is rich in fuel. It is desirable that the crank chamber, together with the annular chamber, *c*, should have a volume bearing a certain proportion to the volume of the cylinder swept by the piston. In order to get this volume a hollow connecting rod is used, built up of two parts, of aluminium or some other light material. This bulky connecting rod occupies a considerable

Fig. 1.

of the cylinder. The port, *u*, putting the annular chamber, *c*, in communication with the interior of the cylinder is at this instant closed by being covered by the piston. On the downward or outward stroke of the piston pressure is exerted on the fluid contents of the crank chamber, and when the piston uncovers the port, *u*, at the end of its downward stroke, and at the same time uncovers the port, *v*, putting the cylinder in communication with the exhaust pipe, *w*. Air and fuel are forced from the annular chamber, *c*, through a port, *u*, into the cylinder. The first fluid to thus enter the cylinder will be pure air or almost pure air, owing to the manner in which the pure air and the air charged with petrol are drawn into the annular chamber and into the crank chamber. A

amount of the volume of the crank chamber. A pipe, *13*, leads from the crank chamber to the diaphragm pump, *14*. The diaphragm pump consists of a vessel having two chambers *15*, *17*, separated by a flexible diaphragm, *18*. The upper chamber, *16*, is in communication with the pipe, *13*, while the lower chamber *17*, is in communication with a valve chamber, *32*. A pipe, *19*, communicates with this chamber, *32*, past a ball valve, *20*, and another pipe, *21*, communicates with the valve chamber past a ball valve, *22*. The pipe, *19*, leads from a water tank, and the pipe, *21*, leads to the cylinder jacket. The upward strokes of the piston draw water into the valve chamber, *32*, and the downward strokes force this water into the cylinder jacket.—October 13th, 1905.

[Weekly, Price 3d.
Post Free, 8td.]

During the past season, the Great Eastern Railway Company, as we have recorded, have put quite a number of motor omnibuses upon various routes connecting up their railway system with points of interest and some pleasure resorts lying outside easy access of their railway stations. These omnibuses have all been built by the Great Eastern Railway Company at their Stratford works, and have proved eminently successful in their running, although in some cases the patronage accorded them has not justified their continuance throughout the winter. Our photograph above shows one of these omnibuses which has been running regularly between Clacton-on-Sea and St. Osyth, one of the best known historical villages in the county of Essex. St. Osyth Priory, which is one of the show places of the district, is the residence of Sir John R. Johnson.

PASSING EVENTS.

The Olympia Exhibition.

IN recent numbers we have referred to the Automobile Exhibition at Olympia which has now opened its doors. This year's Exhibition provides, as everybody expected it would, a record both as regards the number of exhibits and the number of exhibitors, while, as we have previously remarked, a magnificent testimonial to the importance of the English automobile market is provided by the presence of a large number of the 1906 models of leading foreign firms—in spite of the Olympia Show preceding the Paris Salon. There is, therefore, special appropriateness in the fact that King Edward has this year, for the first time, accorded his exalted patronage to the Exhibition.

The Exhibition provides the most satisfactory evidence of the vitality of the automobile industry, particularly in this country, for though types of cars are becoming more and more standardised, there is an equally noticeable display of originality, both as regards engineering details and general design, and a very large number of entirely new models are on view. There is not the slightest indication consequently of any approach to rigid uniformity or stagnation of inventive faculty.

The unprecedented number of the exhibits renders it

impossible for us to deal adequately with more than comparatively few this week, and we have not made any attempt to provide an *olla podrida* of details culled from various sources in advance, since such a proceeding is, in our opinion, worse than useless. With all the more representative types of car, however, we now commence, and will continue in subsequent issues, to deal succinctly but with comprehensive, and as we hope characteristic, thoroughness.

For the benefit of visitors to the Exhibition we are, however, providing a table in this issue which we have compiled from the data with which we have been specially furnished by the exhibitors. It gives in tabulated form all the important elements of practically every car—grouped primarily according to the number of cylinders, and arranged secondarily in their natural order by price. This classification and arrangement will, we think, enable anyone to find the precise type of car that he requires, for it is only necessary for him to glance at the table and he will be at once able to note the numbers of the stalls at which cars of the kind can be seen. Once the numbers are known, the diagrammatic plan that we also give, on another page, will be found to indicate the position of those stalls in the building. This simple arrangement will, we venture to hope, save visitors a lot of time and trouble in finding among the exhibits exactly what they want, and will at the same time be productive of beneficial results to exhibitors, as it will enable intending customers to get into touch with them with the minimum of fatigue and delay. We also give an alphabetical list of the exhibitors denoting the numbers of their stands.

An Apology and a Doubtful Policy.

INDULGENCE is asked, however, both from our readers and from a few stand-holders at Olympia in regard to the list of exhibitors and the diagrammatic plan of the positions of the stands, which are given by us in our present issue. Owing to official objections to providing the Press, as on former occasions, with correct plans and accurate lists of exhibitors, we cannot guarantee that our list of exhibitors and the exact position of every stand in the hall is *officially* complete. As far, however, as it has been, under the circumstances, possible, we have done our utmost to make it reliable, and any omissions there may be, will, we believe, be found to be comparatively trifling. We learn that the official decision is due to the facilities granted to the Press last year not having been used in quite a legitimate manner in the Exhibition buildings, with the result that there was very considerable irritation and the sale of catalogues was prejudicially and unfairly affected.

We hardly think, however, that an exhibition is primarily organised for the purpose of bringing out a catalogue. We have generally understood that shows are arranged to enable the exhibitors to transact as much business as possible, and everything that tends to that end should surely be encouraged.

Of course, if the members of the Society of Motor Manufacturers and Traders, as a whole, desire to limit publicity, and to only allow the numbers and positions of their stands to be buried and hidden away among the voluminous pages of a catalogue, it is for them to decide the question. Their friends, however, and others seeking to do business with them, may thereby have considerable difficulty in ascertaining their whereabouts, and there is more than a possibility of valuable business either being altogether lost or transferred to somebody else, who has been fortunate enough during the buyers'

exploring rambles to "block the way." But this is hardly what is sought. In fact, whatever the Society as a whole may wish, we have found the individual members, and other exhibitors, of a very contrary way of thinking, as in nearly every case there has been a readiness in supplying the information asked for, in marked contrast with the official view adopted by the Society. We cannot regard it as wise to risk the curtailment of business generally at the exhibition out of anxiety lest the sale of a few dozen catalogues might be jeopardised.

Hitherto it has generally been customary with most trade exhibitions, to regard the publication of such information as widely as possible, as of the first importance—in fact, as a rule, full plans, list of exhibitors, &c., are furnished at the earliest possible moment in advance, to induce that very publicity which is rightly regarded as of the utmost importance to the general success of the show. To suppress or unduly limit this publicity, for the sole object of possibly selling a few extra catalogues, which, as a rule, are as incomprehensible to the average visitor as "Bradshaw" to the average traveller by rail, argues, to say the least of it, a want of due sense of proportion.

At the same time, we quite understand that any little privileges accorded by the management for mutual and general good should only be used legitimately, and not abused. But this is a side of the question which should be easily dealt with by the officials on the spot.

A Board for London Traffic.

FOLLOWING upon the report of the Commission on London Traffic, and the publication of the voluminous evidence which the Commission has just put before the public, it is satisfactory to be able to record that the Government have determined to bring in a Bill, presumably at an early date, to establish a Central Traffic Board which shall have the control and co-ordination of all the means of locomotion employed in the Metropolis. It is suggested that the proposed Board should sit permanently, in fact, it is probable that it will resemble in many respects the Local Government Board, and will have under its management or consideration :—

The preliminary examination of all private Bills dealing with locomotion in Greater London.

The improvement of the main roads leading out of London.

The Building Laws as affecting districts not yet built over within the area of Greater London.

The revision and amendment of the laws regulating the breaking up of the streets.

The consolidation and amendment of the laws affecting traffic.

We, of course, do not expect even the ~~creation~~ of such a Board to suddenly introduce order amid the chaos under which the Metropolis has groaned for so long, but the recognition by the Government of the pre-eminent need of a Board whose sole business is to deal with traffic, even if at present only with the traffic of the Metropolis, is an excellent precedent, and encourages us to hope that the whole traffic of the country, and particularly the management of our main roads (as we have always advocated), may ultimately be placed under the supervision of some such central authority.

Materials that Automobile Engineers ought to Watch.

NEARLY every improvement in the manufacture of steel—at any rate, every improvement which has the effect of increasing the strength of that material—is of the highest interest to automobile engineers. For increased strength of material means placing at their

disposal the ability to construct cars of increased power at the same weight or diminished weight for the same power. From this point of view we have in the past devoted a certain amount of consideration to the qualities of nickel steel which render it so valuable a material for the structure of all those parts of a modern automobile, such as crank-shafts, connecting-rods, and valves, which are subjected to severe demands. Recent progress in the metallurgy of steel leads to the conclusion that the alloys of steel with tungsten or wolfram (which are two different names for the same metal) promises to provide a material which for constructional purposes will considerably outclass even nickel steel. Tungsten or wolfram is a rare metal obtained from wolframite, which is by no means a plentiful substance and is not very easy to reduce. Tungsten steels have been for a long time known and employed for high-class machine tools, and when they were first introduced were generally known as Mushet steels. In this capacity they have already rendered great services to the automobile movement, for modern high-class machine tools, which enable steel to be dealt with in the lathe at a speed which would have petrified the engineers of the last generation, are almost invariably made of tungsten steel. The peculiar characteristic of tungsten steels is that they are self-hardening. There is nothing more interesting than to observe a skilful smith manipulating a tungsten steel. At a moderate red-heat it is soft and malleable, and can be forged and cut almost like iron. When it is shaped to the required form it is put aside to cool slowly — never chilled — and by slow cooling attains a degree of hardness which no other steel can equal. In percentages too small to confer this self-hardening property to any noticeable degree, it has, however, recently been discovered that it adds to the tenacity and strength of a steel to a degree which no admixture of nickel can equal. Much comment has been evoked by the manner in which the very light field artillery employed by the Japanese in the late war out-ranged the Russian guns. It has since transpired that the material employed in the manufacture of their ordnance is tungsten steel, and the splendid qualities of this material have enabled them both to diminish the weight of their guns, and to increase their charge, which, of course, means increasing their range. The conclusion seems to follow that the material which enables improvements of this kind to be effected in the case of artillery would be not less effective in meeting the severe demands which automobile construction places upon it, and automobile engineers would be well advised to bear its pre-eminent qualities constantly in mind.

* * *

Vanadium.

AN even newer, and in some respects equally remarkable, alloy is provided, as pointed out by Mr. E. Tucker in a recent paper, read before the Automobile and Cycle Engineers' Institute at Birmingham, by the combination of the metal, Vanadium, with iron. Vanadium is a metal discovered some twenty years ago by Sir Henry Roscoe, at which date it was many times more valuable than gold. Since its discovery, like other rare objects, it has been found in a variety of previously unsuspected places, and is now sufficiently cheap for manufacturers to be enabled to employ a small percentage of it in combination with iron in high-class steels. Its effects when so employed are remarkable, being in some respects similar to the addition of a slightly higher proportion of chromium. Chromium steels, that is to say ordinary

steels containing carbon and iron, with a small percentage of chromium, have for a long time been celebrated for the enormous tensile strength they possess. When chromium is employed in a nickel steel the effects are still more remarkable, and when to this combination is added a small percentage, say 0.15 of vanadium, the increase in the tensile strength and, above all, the tendency to resist shocks and jars in the cold, is increased enormously. Such a steel is an ideal material for use in automobile construction, particularly in crank-shafts and similar parts liable to powerful alternating stresses and strains, and its magnificent properties are certainly calculated to enable the size and weight of parts to be materially reduced. Of course, the economy the improved material admits of must not be carried too far. The object aimed at must be, while slightly economising in weight, to obtain greater strength and reliability, and this, it would appear, vanadium steel enables the manufacturer to accomplish most satisfactorily. The subject is one of high interest to all constructors.

Royal Commission on Motor Cars.—The witnesses called since our last issue went to press are as follows:—Mr. Fitzgerald (assistant secretary to the Office of Works), Mr. F. Fox (of the firm of Sir Douglas Fox and partners), Lord Willoughby de Broke, the Right Hon. Sir James Fergusson, M.P., Mr. W. W. Lupton, of Malton (representing the Yorkshire Union of Agricultural Clubs), Mr. Howard Humphreys (representing the Roads Improvement Association), Mr. Vere Shaw (secretary of the Harness, Horse, and Pony Society), Mr. Henry Norman, M.P., Mr. Arthur Pain, M.I.C.E., J.P. (deputy chairman of the Highways and Bridges Committee of the Surrey County Council), Mr. F. G. Howell (county surveyor of Surrey), Mr. Henry Austin (late of the Wolseley Motor Works, Birmingham), Mr. Pickmere (town clerk of Liverpool), Mr. F. J. Edge (on behalf of the Association of Municipal Corporations), Mr. Thomas Holt (town clerk of Winchester, representing the Non-County Boroughs Association), and Mr. E. H. Hackett (county surveyor of Tipperary).

Motor Union Conference.—A private conference of (a) members of the General Committee of the Motor Union; (b) the chairmen, treasurers and honorary secretaries of affiliated clubs; and (c) the honorary local correspondents of the Motor Union will be held in the reception room at Olympia at three p.m. on Wednesday, November 22nd, the date of the meeting of the General Committee and of the annual dinner. The chief purpose of the conference is to consider and to arrive at a general understanding as to the policy of the Union in connection with the forthcoming General Election.

WE are glad to record, amongst the King's Birthday Honours, that Mr. W. Davis Goff, so well known in connection with automobilism, has been created a Baronet. Since June, 1903, Sir William has been one of the most enthusiastic members of the Motor Volunteer Corps. He was at one time in a cavalry regiment, and his elevation to a baronetcy has been most favourably received in the M.V.C.

[Owing to the enormous pressure on our space this week, we have been compelled to hold over Correspondence and several other regular features.—Ed.]

SOME LEADING CARS AT OLYMPIA.

THE NEW ARROL-JOHNSTON PETROL CAR—PART I.

One of the new Arrol-Johnston Petrol Cars, all of which now have the Engine mounted in front, Multiple-Disc Main Clutches, and Bevel-driven Live Axles.

Now that the time has come when the builders of the Arrol-Johnston cars have decided to widely extend their field of operations, they find themselves in a particularly strong position for doing so. They not only have nearly ten years of valuable experience in motor car construction to their credit, but they have been remarkably successful in the first introduction of their new models to the public—inaugurating the event by winning the Tourist Trophy in the Isle of Man with one car, and securing the fourth place with the other. In Scotland, and, indeed, in the north generally, no surprise would be

felt at any triumphs they might secure, for not only has their earlier type of car become synonymous with "reliability" in the minds of motorists across the border, but the very spirit that now pervades the Paisley works—under the able management of Mr. John S. Napier—is alone calculated to inspire confidence.

In the south, it is, perhaps, not so generally remembered that these makers have for many years turned out a remarkably useful type of vehicle, for the car itself was more especially adapted to local requirements in Scotland, and its development proceeded, in consequence,

Fig. 1.—View of the 12-15-h.p. Arrol-Johnston Chassis, showing the general arrangement of the entire mechanism. This smaller Model has the maker's well-tried twin-cylinder, horizontal, balanced Engine placed beneath the Bonnet in front.

Fig. 2.—Side Elevation of the 12-15-h.p. Arrol-Johnston Chassis.

along somewhat different lines to those with which most motorists are familiar. The nature of the country and the general character of the climate demanded something different during the earlier days of the industry, and the Arrol-Johnston dog-cart, with its high build, compact design and solid tyres, was admirably calculated for standing rough roads and for constant use in wintry weather, where and when many another car would be brought to a standstill.

It is significant, too, and is therefore worthy of more than passing notice, that the Arrol-Johnston dog-cart never underwent any great alteration in general design since it was first described by us in September, 1901, for not only is this an excellent testimony to the engineering skill of the Arrol-Johnston firm, but it is a strong proof that their early model possessed features of exceptional merit. Curiously enough—though apparently few motorists know it—at least two of the supposedly novel characteristics of the very latest up-to-date cars built by other makers have for many years been standard practice on this Scottish dog-cart. We refer to the construction of the live-rear-axle, which not only has roller-bearings, but carries the road-wheels in such a way that the weight of the car is taken direct on the projecting axle-tubes, and to the method of lubricating the entire engine from a pump in the base of the crank-chamber, through oil-passages drilled in the various moving-parts. The two chief portions of that car—the engine and the back axle—have, indeed, been mainly responsible for its remarkable popularity, and it is but natural, therefore, that the makers should now retain them as far as possible on the more orthodox new models which they are putting on the market. It should be remembered that both have stood up extremely well under the exceptionally severe strains imposed by solid rubber tyres, and that, even if the twin-cylinder engine is unlike that on other vehicles, it has stood the test of time and has given every satisfaction.

The Paisley Works.

A word should, moreover, be said, in this preliminary introduction, concerning the manufacturing facilities that are available at Paisley, for there are few works devoted to the manufacture of cars in this country which can boast of a better equipment of modern plant for the purpose, or of a more thorough system of organisation throughout each and every department. Already, the floor space amounts to about $4\frac{1}{2}$ acres, and it is intended to make such extensions that the buildings will shortly

cover the whole $6\frac{1}{2}$ acres of ground owned by the company. Efficiency, regardless of initial outlay, is the keynote in this large factory, where a special study has been made of every modern method for producing on a large scale at a low cost, for securing special materials for special purposes, and for turning out absolutely interchangeable parts. Very remarkable is the equipment of machine tools that has been laid down, and is constantly being added to, while the cutting-speed at which they run denotes the attention that has been given to recent developments in the steel industry. Every part that is required for the manufacture of complete vehicles is made on the premises, with such few exceptions as springs, tyres, and lamps. The New Arrol-Johnston Company have, for some time, even built all their own magnetos.

The New Models.

With the advent of the new models, the firm's dog-cart is no longer to be manufactured, so that there will be no Arrol-Johnston car in future that does not appeal to motorists in all localities. For some time past, this change has been anticipated, but it was not until the makers were satisfied that they could still further extend their reputation with a more universally appreciated type of car, and could build an even more satisfactory kind of vehicle, that the change was finally decided upon.

Even now, most of the best features of the dog-cart have been retained, in a more or less modified form, on all the new cars, and the same form of engine is used on the new twin-cylinder car. This engine is of a special balanced type, with a pair of horizontal cylinders, each of which has two pistons, and has proved itself to be so satisfactory that it was considered useless to attempt to build an equally good twin-cylinder engine of the ordinary vertical pattern.

Two types of pleasure car are now being turned out, and in addition to these is a heavy commercial vehicle, the chassis of which has been specially designed for motor 'bus work. The smaller pleasure car is that fitted with the horizontal engine just referred to, and is practically identical with those that ran in the Tourist Trophy race. The engine gives 12-h.p. at 800 revs. per min., and is easily capable of developing 15-h.p. at its maximum speed of 1,100 revs. per min. The larger car has a 4-cylinder vertical engine, which gives 24-h.p. at 950 revs. per min., and is rated at 24-30-h.p. This same engine is also used for the 'bus chassis.

Both cars are of much the usual live-axle type in general respects, with the engine fixed in front beneath

Fig. 3.—Plan of the 12-15-h.p. Arrol-Johnston chassis.

a bonnet, with a main clutch between it and the gear-box, and with a propeller-shaft and bevel-gearing to drive the road wheels. Except in minor details, and in the size of the various parts, the design of the two is moreover identical, though the larger car has an additional transverse spring at the back, and has a somewhat differently arranged change-speed-gear.

The 'bus chassis also follows the same general lines up to a point, although the frame is so very much larger and stronger, for the engine, clutch, gear-box, propeller-shaft and differential-shaft of the 24-30-h.p. car are used on it, though the differential-shaft does not form its back axle; it constitutes a countershaft instead, and the power is transmitted from it by short side-chains to the road-wheels. The external casing is carried by strong tubular radius-rods that tie the axle to the side-members of the frame, and there are other novel points about the suspension which will be dealt with in due course.

All these models are the outcome of the prolonged experience of which we have already spoken, both in the matter of design and of materials, while a very high standard of workmanship can be relied upon. Not merely reliability for a time is aimed at, but the makers have taken care to ensure that all parts shall be really durable. Although, probably, a large percentage of their customers will prefer to have pneumatic tyres fitted to

the pleasure vehicles, the entire mechanism is of such a nature that solid tyres can safely be employed by those who prefer to take advantage of them; the Arrol-Johnston Company strongly advocate their adoption on the driving wheels, and it should be remembered that they are well accustomed to the use of them.

Neither type of touring car is intended merely for good roads, for fine weather, or for attaining high speeds, but both have been designed as comfortable vehicles for everyday use. They are, as a rule, fitted with roomy side-entrance bodies, seating four or five persons, and they leave nothing to be desired as regards general appearance. The bodies are hinged at the back so as to render the entire mechanism thoroughly accessible, and the mechanism itself is so constructed that any part can be readily inspected.

The 12-15-h.p. model has an 8 ft. 9 in. wheel-base with 810 by 90 mm. tyres, while the wheel-base is 9 ft. 6 in. on the 24-30-h.p. car, with 915 by 105 mm. tyres. In both cases, four forward speeds and a "reverse" are provided by the sliding spur-wheels in the gear-box, and, on the fourth gear, there is a direct drive from the engine to the axle. The tank capacity is sufficient for running a distance of about 200 miles without any replenishment.

(To be continued.)

THE 1906 GLADIATOR CARS.

SEVERAL important alterations have been introduced into the new Gladiator models, which will now include both live-axle and chain-driven types. In all there will be six different chassis, ranging from 10-h.p. to 30-h.p. Of these, the three least powerful have live axles, while the others retain the chain drive which has hitherto been standard on all Gladiator cars. The 10-h.p. and 12-h.p. vehicles have twin-cylinder engines, but the others are of the four-cylinder type with the exception of the new 30-h.p. car, which has a six-cylinder engine.

The main frame is now of pressed steel, and the underframe no longer extends forward beneath the engine, being only employed on the new models for supporting the gear-box. The suspension, however, is still the same as formerly, and the leaf-spring spring-hangers which formed a prominent feature on last year's models are retained on the new cars.

Another important change is the substitution of the "Mercedes" for the "Panhard" type of gear-box on the 18-h.p. model, and also on those which are more powerful. In other respects, the transmission system remains as before, and the differential casing is, it will be noticed, still made separately from the gear-box proper. The side-chains, on those cars which have them, are now entirely enclosed, ball-bearings are fitted throughout the transmission, and a multiple-disc clutch is again one of the important features.

Aster engines are only used on the two smallest cars, for the Gladiator Company build the larger engines themselves. On the 18, 24 and 30-h.p. engines, a variable lift device is fitted, and another feature on the new models is the Gianoli high-tension magneto—a description of which is now appearing in our columns. A honeycomb radiator replaces the coiled tube type used in the old models.

THE LATEST NAPIER CARS—THE 6-CYLINDER MODELS.

It needs, to-day, but a brief visit to the Napier Works at Acton to prove how justified has been the policy adopted by Mr. Edge and Mr. Napier in restricting their attention to only the very best in motor car construction, and it similarly needs only a short run in one of their latest vehicles to convince the most sceptical of the remarkable advantages that can be derived from a six-cylinder engine. It is but a few years ago that even the most enthusiastic manufacturer would have regarded present-day prices as being — commercially — quite impossible, and, however sanguine he might therefore have been concerning the future of the industry, the beautiful

workmanship and costly construction put into some of our best modern vehicles would have seemed to him quite impracticable. Similarly, it may be remarked that only a year ago, six-cylinder engines appeared to be merely a passing craze to many well-informed people, some of whom had, even then, very good reasons for looking upon four cylinders as being inconveniently many. It so happens, however, that the Napier Works have assumed enormous proportions—of which the buildings last described at any length in these columns are but a very small part nowadays—and it also so happens that by far the greater number of cars that are being turned out in this remarkable factory have six-cylinder engines.

Fig. 1.—Front View of the 60-h.p. 6-cylinder Napier Car, which is of the Live-axle Type, and incorporates all the latest refinements of design and improvements of construction.

ing, and remarkable is the trouble that is taken to obtain the best results. The latter is, perhaps, especially striking to those who are fairly well acquainted with the majority of works in this country, for it is not all firms that can afford to place essence of refinement so very far before cost of production. One ceases to wonder why it is that a six-cylinder Napier runs so smoothly after witnessing its manufacture.

On the general subject of six-cylinder engines, it may at once be said that their success or failure depends entirely upon how they are designed and built, for although this statement has at first the appearance of being a mere platitude, its applicability becomes more and more pronounced with each additional pair of

Much more could be written both with regard to the works and upon the merits of six-cylinder engines than would alone fill the space at our disposal, and, therefore, these two interesting subjects must be dealt with quite briefly in order to allow of passing on to a description of the latest Napier vehicles. Concerning the first, it may be said that the equipment of modern tools and of up-to-date appliances is even more complete (in the light of the knowledge of the day) than it has been at any previous period. We have seen no finer workmanship or finish in any other automobile factory. Numerous are the special tools for ensuring absolute accuracy of machin-

Fig. 2.—View of the 60-h.p. Napier Chassis from the "off" side, with the Bonnet removed to show the 6-cylinder Engine.

Fig. 3.—The 60-h.p., 6-cylinder Napier Chassis. View from above.

cylinders. Expressed more definitely, absolute synchronism between cylinder and cylinder is all important if smooth running and regular action are to be ensured, while there are so many ways in which a lack of true synchronism can be allowed to creep into a multi-cylinder engine, that special care and special skill are essential down to the veriest detail. Provided that all these things have been duly attended to, the many more or less obvious advantages resulting from three overlapping impulses, during each revolution, can be secured to the full.

Owing to the greater constancy of the turning moment on the crank-shaft, a much lighter fly-wheel can be used, while another important consideration is that less wear is imposed on all gear-wheels and upon the tyres. The lighter fly-wheel—about half the weight of that needed by a four-cylinder engine of equivalent power—naturally permits the speed to be varied much

more quickly; the frequency of the explosions facilitates getting under way with great smoothness, as well as giving silence and comfort at all times; and the constancy of the suction on the carburettor renders its action almost continuous. It is the ignition apparatus that has naturally presented the greatest difficulties in the past, but the mere fact that the 40-h.p. Napier engine has shown itself capable of driving its car when running at any speed between 240 and 2,100 revs. per min. shows very clearly that this difficulty has been overcome.

The 1906 Models.

No less than three distinct models are now being turned out, for in addition to the chain-driven 40-h.p. car—of which we gave full particulars when it was first introduced—there is now a similar 40-h.p. live-axle vehicle, and also one having a 60-h.p. engine.

THE N.E.C. PETROL CARRIAGE.

AMONGST the entirely new types of vehicle which are to be on view at Olympia, that which is being built at Acton by the New Engine Company will be examined with much interest by most visitors. It is of very novel construction throughout, and is either fitted with a double landaulette body or with a special form of hooded body that is termed an "Alexandra." Whichever style is preferred, it constitutes a very handsome carriage, that is quite suitable for town use in the parks, while its speed capabilities are ample for general touring work in the country.

No semblance of a bonnet is needed, since the 4-cylinder engine, with its opposed horizontal cylinders of $4\frac{1}{2}$ in. bore by $4\frac{1}{2}$ in. stroke, lies compactly between the side members of the frame, beneath the front seat, where its valves and ignition-plugs are very accessible through the panelled doors at each side. Practically no portion of the driving mechanism is visible externally,

for the main frame, with the body, is slung on an unusually low level, and is carried well within the axles. Simple leaf-springs project from each corner of the pressed-steel frame, those at the rear being fixed beneath, and those in front above, the axles; spring torque-rods are also introduced centrally to tie the axles to the frame.

Immediately behind the engine is the fly-wheel, and close behind it is the change-speed mechanism; the latter is of the epicyclic type, providing a direct top speed, one hill-climbing gear and a "reverse." The gear and the engine are both fixed to an independent framework, which is in turn secured to the main-frame with a three-point suspension. From the change-speed-gear, the power is transmitted to the "live" rear-axle by a universally-jointed propeller-shaft and worm-gearing, the worm lying in the base of the axle-casing, beneath the differential.

The engine develops about 30-b.h.p. at its normal speed of 1,250 revs. per min., and the car is either geared to run at 27 or 35 miles per hour, according to requirements. The power available is thus sufficient to enable the top gear to be used under all ordinary running conditions, and this is facilitated by the simple method that is adopted for controlling the engine. Not only does the governor automatically "time" the ignition, but any desired speed is maintained by it; a single hand-lever on the steering-pillar "sets" the normal speed, and the same pedal that disengages the clutch reduces the engine speed initially.

Each piston is fed with oil direct from a large lubricator on the dashboard, but all the other moving parts are

supplied, through the hollow crank-shaft, from a pump in front of the crank-chamber. The circulating water is cooled by a honeycomb radiator placed on a rather lower level than usual close up to the dashboard, and a gear-driven fan draws the necessary air through it.

In spite of the position of the engine, every part is readily accessible, for the upper portion of the crank-chamber—although it contains the cam-shaft and push-rods—can be bodily removed in a few minutes.

Normally, the car has wheels fitted with 36-inch pneumatics, but the vehicle is designed to take 40-inch rear tyres if preferred, and to use solid rubber tyres. The wheel-base is 10 ft. 2 ins., and the track is about 4 ft. 9 ins.

THE 1906 THORNYCROFT CARS.

The 24-h.p. Thornycroft Car.—View of the Chassis from above, showing the suspension of the Gear-box and the position of the Band-brake at the end of the Propeller-shaft.

HITHERTO only one model, and that a comparatively high-powered car, has been manufactured by the Thornycroft Company, but for next year a lighter and less powerful chassis is being turned out, so that an even larger number of motorists than before will find that this well-known type of car comes within the scope of their requirements.

The new model is the same as the Tourist Trophy car, while the larger chassis is similar to that which we described on February 11th this year; the latter is still fitted with the 24-h.p. engine, in which the cylinders are cast separately, with their valves arranged symmetrically on opposite sides, and low-tension igniters fitted as plug fittings over the inlet-valves. The general arrangement of this chassis is clearly indicated in our illustration, which is a view taken from above. The pressed steel frame, it will be noticed, is narrowed some considerable distance behind the dash, and an underframe is provided for the support of the engine and gear. Radius-rods are now hinged to this underframe, and pass rearwards to the live-axle casing, but a separate torque-rod is also provided. Both hand and foot brakes are operated through wire cables; the latter is fitted on the propeller-shaft close up to the differential casing.

On the 14-h.p. car—of which the Tourist Trophy chassis was illustrated on September 9th and 16th—the engine is entirely different, although the other general features do not differ greatly from the 24-h.p. vehicle. The engine has its four cylinders cast in one piece, and all the valves are arranged in the cylinder heads. The cam-shaft, also, lies alongside the top of the cylinders and operates the valves by short rock levers. The low-tension magneto and the circulating pump are driven by a transverse shaft in front, and the high-tension distributor for the battery ignition is mounted behind the dash, and is driven by the cam-shaft. The low-tension igniters are operated from the same cam-shaft as the valves, and their tappet levers are carried by detachable plates, which can be easily removed from the side of the cam-shaft casing, for which they also form inspection covers. The valves themselves are made with bayonet-socket fittings in order to make them very accessible, and they can, by this arrangement, be bodily removed with their seats in a few seconds. Special care has been taken to keep these valves cool, by ensuring that as large a surface as possible comes in direct contact with the water-jacketed cylinder casting.

THE BIANCHI PETROL CAR.

Fig. 1.—The Bianchi Car.—Side view of the 16-22-h.p. Chassis, showing the Metal Sheathing beneath the Engine and Gear. The very long rear Springs are prominent in this view.

ITALY is already famous for the excellence of the cars which have been turned out there, and the latest introduced into this country, the "Bianchi"—for which Messrs. Straker and MacConnell have the sole agency—has every appearance of maintaining the very high reputation already earned by Italian vehicles.

At the present time two models only are being manufactured, viz., 16-22-h.p. and 24-40-h.p., but as these are similar, except in dimensions, the description which we give of the smaller model will apply equally well for the other also. There are no radical innovations in the general design, nor in the construction of the minor parts, but the car is thoroughly up-to-date and well made in every respect. Both models are of the chain-driven type, with four-cylinder engines and four-speed gear-boxes.

The Frame and Transmission.

The frame, which is of pressed steel, is narrowed in front of the dash in order to secure a wide steering lock, and is stayed by perforated transverse members, which have a channel section. Semi-elliptic springs are employed both in front and behind, but those behind lie outside the frame, and are of great length. The front axle is bent, and has plain ends, the forks for the steering-heads being formed on the hubs of the front wheels instead. The tie-rod connecting the steering-knuckles lies behind the axle, the steering-gear itself is of the worm and sector type, and the joints in the connecting-rods of the steering mechanism are of the ball and socket type. The road wheels run on ball-bearings, which are also

Fig. 2.—The Bianchi Car.—View from above of the 16-22-h.p. Chassis, showing the suspension of the Gear-box and the position of the Petrol-tank at the rear of the Chassis.

on the differential countershaft. The internal expanding brakes on the rear hubs are connected to a side lever.

The Engine.

The engine has its four cylinders cast in pairs and the valves are arranged symmetrically on opposite sides. The bore and stroke of the small model are 105 mm. and 130 mm. respectively, while on the larger car the engine has a bore of 125 mm. and its stroke is 150 mm. Inspection plugs are fitted above the valves, and cocks are provided in the cylinder heads. Fitting diagonally into the inlet-valve-chambers are the low-tension igniters, which are operated from exposed cams on the inlet-valve cam-shaft. The lower ends of the tappet-rods are provided with rollers, which rest in contact with the cams. The rods themselves are anchored by links, A¹, Fig. 5, to a rock shaft, A, which is connected to the timing-lever above the steering-wheel. Rocking the shaft, A, thus alters the position of the roller relatively to the cam, and advances or retards the ignition accordingly. The gear-wheels which drive the cam-shafts are situated in front, and are completely enclosed. On the centre of the exhaust-valve cam-shaft is another enclosed gear-wheel, which drives the circulating pump and the magneto; the latter is visible in Fig. 4. The radiator is of the honeycomb type, and is composed of exceptionally small square tubes.

The carburettor, which is prominent in Fig. 5, is pressure-fed from the large petrol tank at the rear of the chassis. The throttle-valve is of the horizontal

Fig. 3.—The Bianchi Car.—View, from behind, of the 16-20-h.p. Chassis, showing the Dashboard and the perforated cross-members of the Frame.

used throughout the transmission. The gear-box is carried on a three-point suspension, being attached directly to both side members of the frame in front, and to one of the transverse members behind. Four speeds and a reverse are provided by means of two sliding members on the driving shaft, and the gear lever, therefore, works in a "gate" type of quadrant. The clutch is of the multiple-disc type, and is enclosed in the fly-wheel, which is of large diameter, and has fan-shaped arms. Between the clutch and the gear-box is a rigid propeller-shaft, coupled up with a short length of flanged shafting in order to facilitate the removal of the clutch. The clutch itself is very easily adjusted, for its spring is exposed and is in an accessible position.

Both clutch and brake pedals are of the "push" type, and the latter operates a shoe brake

Fig. 4.—The Bianchi Car.—View of the 16-20-h.p. Engine, from the Exhaust-valve side, showing the Low-tension Magneto.

sleeve type, and has an extra air-port which uncovers as the throttle-valve opens. The throttle-valve is inter-connected to a hand-lever above the dash, and can also be opened by an accelerator-pedal.

Situated on the dash, is a small handle, B, which operates the spindle, B', to regulate the effective size of the petrol jet in the carburettor.

Lubrication of the engine is effected through a neat sight-feed fitting on the dash, from a small pressure-feed tank fixed to the side of the frame. Care has been taken to protect the entire machinery from mud and dust, for which purpose it will be noticed from our illustrations that a metal sheathing is fitted beneath the frame for the greater part of its length.

Fig. 5.—The Bianchi Car.—View of the 16-20-h.p. Engine, showing the Carburettor and the Low-tension Tappet Mechanism, which is timed by rocking the Shaft, A.

THE "BROTHERHOOD" PETROL CARS.

Several Novel Features, and a Larger New Model.

ALTHOUGH the many good and distinctive points of this year's 20-h.p. "Brotherhood" have been retained, several improvements have been made in readiness for next season. All are, however, additions rather than alterations, and, consequently, the very full description that we gave at the time of the last Olympia exhibition needs but little revision.

The 40-h.p. Car.

Also similar, except as regards size and one or two comparatively minor details, is the new 40-h.p. model, which is now making its appearance for the first time in public. Even in point of view of length, its wheel-base is but one inch longer (9 ft. 10 in.) than the long-frame 20-h.p., but every part is stronger, and the foot-brakes, as well as the hand-operated brakes, act direct upon the hubs of the

road-wheels. The former brakes lie inside, and expand outwardly against, the same brake-drums that are encircled by the latter.

One of the few differences in general design between the 40-h.p. and the 20-h.p. engine is that the more powerful model has a special arrangement of the cam-shaft to enable the compression to be reduced at starting.

The same pedal-control, acting on the variable-lift inlet-valves, and the same automatically "timed" ignition are employed for simplifying its regulation. Its cylinders, however, have a bore of 5 inches, instead of 4 inches, and the stroke is 6 inches, instead of 5 inches.

The Modified Transmission-Gear.

The main clutch is one of the chief departures from

One of this year's 20-h.p. "Brotherhood" Cars, which has now run some 7,000 miles without giving the slightest trouble. Its enthusiastic owner is Mr. Fred. Kelley, of Sheffield.

Fig. 1.—The 1906 "Brotherhood" Change-speed-gear, the lower portion of which carries the whole mechanism, intact with its Ball-bearings. The upper casting, which has been taken off in this illustration, consequently merely serves as an oil-tight cover, and it is even possible to allow the gear to run without it, should it ever be desirable to do so.

this year's practice, for that of the leather-faced cone type has now been replaced by the multiple-disc "Bradley," of which a very full description has already appeared in these columns. Hardly less noticeable, moreover, is the important change that has been made in the gear-box itself and in connection with the differential countershaft, special ball-bearings being fitted to all three shafts. Figs. 1 and 2, enable these to be seen, the former showing the gear-box with the upper portion removed, and the latter being a view from the end of the countershaft.

In the gear-box, the bearings are so arranged that they remain undisturbed in any way, even when fully exposed to view, the upper portion of the box merely serving as an oil-tight cover; it is rendered oil-tight by flanges on the shafts. In Fig. 2, one of the large ball-bearings, A, that support the ends of the countershaft is visible through the combined brake-drum and sprocket-wheel.

Improved Radius-Rods.

Instead of merely hinging the radius-rods, B, to the axle and to the countershaft-bearings, the radius-rods can now ride freely, and take a concentric bearing, about the axle and the countershaft. In this way, they not only maintain an absolutely constant distance between the sprockets and the chain-wheels, and so keep the chain equally tight at all times, but they can be allowed to project rearwardly behind the back axle. The projecting portions carry the brake-operating toggle-levers—as seen in Fig. 3—and

the brake-bands, C, are entirely carried by the radius-rods. The position now occupied by the long springs, C', that act against the hand-lever, will also be noticed.

A further change has been made in connection with this portion of the new vehicles, for the brake-drum now lies between the chain-wheel and the road-wheel, both registering with the hub of the road-wheel to ensure trueness of running. This constitutes a much more compact arrangement, and does away with the distance-pieces formerly employed.

The Ratchet-Sprag.

Visible in Fig. 3, is the pivoted pawl, D, that replaces any ordinary kind of sprag. It acts direct upon the "off"-side road-wheel, and is controlled by the small hand-lever, D', shown in Fig. 5. In Fig. 4, the internal ratchet-wheel, D'', with which the pawl engages—inside

Fig. 3.—Three views of the rear, off-side portion of the 1906 "Brotherhood" Chassis, demonstrating the manner in which the new Radius-rods, C, carry the Hub-brakes; the Brake-drums are located outside the Chain-wheels, and the Sprag-Pawl, D, is fitted so as to engage with the Ratchet-wheel inside the Brake-Drum. A portion of the corrugated Petrol-tank, which is one of the features of these cars, is also visible in the upper illustrations.

cally moved back into its neutral position by the gear-lever, E, when that lever is "reversed."

A New Induction-Coil.

The ignition system itself has undergone no change—except that the position of the plugs has been slightly altered—but an extremely interesting type of induction-coil (the "Bradley") is now used instead of a trembler coil on the 1906 vehicles. This coil differs primarily from all others with which we are acquainted, inasmuch as it gives but one spark, instead of a series, each time that the commutator completes the low-tension circuit. A magnetic switch-device operates the contact-breaker, and this forms an integral part of the complete apparatus. The advantages claimed are two-fold—a saving of current, and a great improvement in synchronism. Current is saved because the primary circuit is instantly broken, by the magnet, immediately after it has been completed by the commutator, and more complete synchronism is possible between cylinder and cylinder—especially at very high speeds—

Fig. 2.—Side view of the central portion of the 20-h.p. "Brotherhood" Chassis, showing the Ball-bearing, A, supporting the end of the Differential Countershaft, and also a portion of the adjustable Radius-rod, B, that now encircles the Countershaft and the Rear-axle.

the brake-drum—stands out very clearly, and the spring, D¹, that holds the pawl clear of the ratchet-wheel will be noticed in Fig. 3.

This ratchet-sprag is connected with the hand-lever, D³, by a steel cable, and the lever itself is carried by the same quadrant as the gear-lever, E, and the brake-

Fig. 4.—A "Brotherhood" Driving Wheel fitted with its combined Brake-drum, Chain-wheel, and Ratchet-wheel. These parts register with the Metal Hub, and are bolted to each alternate Wood-spoke.

lever. For guarding against any risk of damage being done, by attempting to "reverse" the car when the sprag is in play, the very wise precaution has been taken of fitting the lever, D³, in such a way that it is automati-

Fig. 5.—View of the Side Levers on the "Brotherhood" Chassis. The small Lever, D³, controls the direct-acting Ratchet-sprag, on the "off" Driving-wheel, and is automatically held in its neutral position whenever the Gear-lever, E, is caused to introduce the "Reverse" gear. The Hooter-bulb above the Steering-wheel is a characteristic of all "Brotherhood" Cars, the Engine-control on which is by a single Pedal only.

because the contact-breaker always starts from rest, instead of being, to all intents and purposes, constantly trembling.

THE WOLSELEY AND SIDDELEY TOURING CARS FOR 1906.

THERE is little that even the most exacting motorist can require, either as regards size or type of pleasure vehicle, that the Wolseley Company cannot now supply from their extremely comprehensive list of standard cars. Their programme for the coming year includes no less than nine distinct types, and as three of these are made in alternate lengths of chassis, there is, in all, a choice of twelve different models. This is not everything, however, for votaries of the live-axle are now catered for as well as those who still favour the chain-drive; while both the horizontal and the vertical types of engine find their appointed places among these numerous types.

The "Wolseley" and "Siddeley" cars are made in the 6, 8, and 12-h.p. engine need the power of the famous of the

twin-cylinder car. The larger vehicle has four cylinders, but is in other respects similar in design. The gear-box is very short, and has two sliding members, which give three forward speeds and a reverse. The gears are operated by a lever working in a double-slotted quadrant, and a direct through drive is provided on the top speed.

The engines on both models resemble others of the Wolseley and Siddeley type, in having aluminium jackets with cast-iron liners and separate heads, which are independently water-jacketed. A ground joint is made between the head and the cylinder. The inlet-valves have a variable lift device, and they are fitted

Fig. 1.—The 12-h.p. Siddeley Car.—Elevation and Plan of the Chassis, showing the Live-axle and the Three-point Suspension of the Engine and the Gear-box.

Show. The most powerful of these three chassis is, however, a comparatively new model, for it first appeared, in its modified form, in the Tourist Trophy Race. It does not differ materially from the standard Wolseley practice, the only important innovations being the mechanically-operated inlet-valves, and the governor, which acts on the throttle.

The Siddeley cars are now made in six standard sizes, viz., 12, 15, 18, 25, 32, and 70-h.p., and of these the two which are least powerful have live-axes. The general design of these two models is clearly indicated in Fig. 1, which represents an elevation and plan of the smaller

above the exhaust-valves, while the engine itself is carried on a three-point suspension. Ordinary battery ignition is provided on the 12-h.p. model, but a high-tension magneto system is fitted on the 15-h.p. car instead.

The general features of the chain-driven Siddeley cars—which include all models above 15-h.p.—have been described by us in the past, but an important change has now taken place in the transmission system of the new models. Instead of the "Panhard" type of gear previously employed, the "Mercedes" principle of a divided sliding-sleeve has been adopted, and the gear-box resembles in this respect that used on the live-axle cars; no direct through drive to the differential countershaft is, however, provided on the chain-driven vehicles. Another modification is the separation of the differential

* For the description of the 6-h.p. Wolseley car, see THE AUTOMOTOR JOURNAL, May 7, 14, and 21, 1904. The 8-h.p. model was described in February last.

as it always has done in the Siddeley and Wolseley vehicles, right up to the sprockets outside the frame.

The new features, other than those just mentioned, on the 18-h.p. Siddeley—which is already a familiar model to the motoring public—are a slightly larger engine, which is carried on a three-point suspension, and the adoption of double-ported inlet-valves instead of the plain mushroom type previously used. High-tension magneto ignition is also an innovation on this car.

The 25 and 32-h.p. models are quite new, and their engines are dissimilar to those of the other types, for the cylinders are separate, and are cast in one piece with

their heads and water-jackets. The induction valves are similar to those on the present 18-h.p. model, and they have, like all the Siddeley cars, a variable lift mechanism by which the engine is controlled. A three-point suspension is not in this case provided for the engine, but an important feature in its construction is that the lower half of the crank-chamber is detachable without affecting the crank-shaft. Low-tension magneto is the standard form of ignition on these two models, but an alternative battery system can be provided if required by the purchaser—as with the 15 and 18-h.p. vehicles.

Stand 115a.

THE AUTOMOTOR JOURNAL stand at the Olympia Show is 115A, on the ground floor of the south side of the Hall, near the Hammer Smith Road entrance.

THE proposed establishment of a Winter Sports Club at Olympia has, we understand, given rise to the impression that the annual Motor Exhibition will no longer be held there. This is incorrect. The Society of Motor Manufacturers and Traders will continue to hold their exhibitions in Olympia every November, their position with regard to the building for future shows being absolutely assured.

His Majesty's New Car.—At the Olympia Show, the Daimler Company's chief exhibit, is the new 35-45-h.p. Limousine that has been specially built by them for H.M. the King. It is a beautifully finished six-seater, luxuriously fitted with folding luncheon table, electric lights, and revolving easy chairs.

Bonus for Chauffeurs.—Messrs. Jarrott and Letts make an attractive announcement, in connection with their De Dietrich cars, which is of interest to drivers of these vehicles. They purpose giving away the sum of £100 as prize money. The exact details of their scheme are for the present withheld, but will be available to applicants at the De Dietrich Stand.

THE 1906 DAIMLER CARS.

Fig. 1.—One of the latest Daimler Cars.—View of the Chassis, as seen from above, with the upper and lower portions of the Gear-box removed.

A FEW improvements have been made in the standard design of chassis, but otherwise the Daimler Company have not found it necessary to make any alterations in their famous models for next year. They make the frame in three lengths—to give a wheel-base of 8 ft. 6 ins., 10 ft., or 11 ft.—and they build three engines of different power to suit it. There are thus practically nine distinct types of chassis, which are identical except in length, power, and in the strength of axles, springs, wheels, and frame. A typical chassis, as seen from above, is shown in Fig. 1.

All three engines are of the 4-cylinder type, and are similar in design to those of this year, except that now they have an additional shaft—on the opposite side

to the cam-shaft—for driving the pump; this shaft, which is visible in Fig. 3, also serves for the magneto, when an auxiliary ignition system of that character is required. The three engines develop 28, 30, and 35-h.p. respectively, at normal speed; views showing their construction are given in Figs. 2 and 3. Another alteration of an important character relates to the single-lever control-mechanism for the throttle-valve and the timing-gear, by which the richness of the mixture is varied to suit all and every position of the throttle-valve, and the ignition is simultaneously retarded or advanced to give full power.

Various refinements have been introduced in connection with the leather-faced cone-clutch, with the

Fig. 2.—One of the 1906 Daimler Engines. View from the left side, showing the interconnected Throttle-valve and Timing-gear.

Fig. 3.—View of a Daimler Engine, from the right side, showing the additional Lay-shaft for driving the Pump—and the Magneto also (when required).

result that less pressure is needed on the pedal than formerly. Another new feature on the latest cars is the provision of a safety-catch on the "reverse" lever, to prevent a forward speed from being brought into play when the reversing pinion is in mesh.

The compensating and operating mechanism for the hub-brakes remains unchanged in design, but it is now raised up higher from the ground, and is therefore more

fully protected from mud and dust, besides being more out of the way. The hub-brakes themselves, as also those close up to the sprockets on the ends of the countershaft, have undergone no change.

It will thus be seen that such modifications as these are, are all of a minor character, which is in itself an excellent sign. It indicates that the makers and users alike have had every reason to be satisfied with this year's cars

THE 1906 PANHARD CARS.

DEVOTEES of the six-cylinder engine will welcome the new model which Messrs. Panhard and Levassor are including in their list of cars for 1906. It has a six-cylinder engine which is rated at 50-h.p., but in other respects the design of the chassis follows standard Panhard practice. The engine—which is shown in Fig. 2—has separate cylinders, and it is made in two types, one having steel cylinders with copper water-jackets brazed round them, and the other having each cylinder cast in one piece with its jacket. The valves are arranged symmetrically on each side, and they have inspection covers above them which are held down by yokes. The

engine itself is carried on an angle-iron underframe, which extends as far as the first transverse member

The 50-h.p. Panhard Car.—Front view of the new 1906 model which is fitted with a six-cylinder engine.

for the body. A multiple-disc-clutch is enclosed in the fly-wheel, which has fan-shaped arms, and a short

behind the dash. High-tension magneto ignition of the Eisemann type is provided, and the ignition-plugs are fitted horizontally into the inlet-valve chambers, which are, it will be noticed, all connected together by a straight copper pipe communicating with the carburettor. The carburettor is of the Krebs type and the main throttle-valve is governed automatically by hydraulic pressure from the circulating pump which is gear-driven.

The main frame is constructed on the usual Panhard lines, from flanged steel flitch plates, which are reinforced with wood to stiffen them and to form a substantial foundation

Fig. 1.—The 50-h.p. Panhard Car.—Side view of the Chassis, showing the Steering Column which passes through the Dash.

flanged-coupling is provided in the shaft between the clutch and the gear-box to enable the former to be more easily removed. The gear-box is similar to that used on the 24 and 35-h.p. models, and our illustration, Fig. 3, shows its peculiar shape, and the three-point suspension by which it is carried from two of the transverse members of the main frame. Both shafts in the gear-box are carried on ball-bearings, four speeds and a reverse are available, and the top gear is a direct-through drive to the differential countershaft.

In all, five models are to form standard types for next year, these having engines of 8, 15, 24, 35,

Fig. 2.—The 50-h.p. Panhard Car.—View of the six-cylinder Engine, showing the Kretz's Carburettor and the Hydraulic Governor, A, which opens and closes the Throttle.

engines. No alterations have been made in the smallest model, but some modifications in detail are embodied in the other types. All these cars are now fitted with ball-bearings in the road-wheels, and have hydraulically-governed throttles operated from gear-driven circulating pumps. High-tension magneto ignition is fitted as formerly, but the Eisemann magneto has been specially constructed so that the magnets now rock bodily about the armature for the purpose of "timing." On the 24-h.p. and the more powerful models, the pedals are arranged to be pushed forwards instead of pressed downwards, while another slight modification is that all the new models have the steering column projecting through the dash.

Milan International Exhibition, 1906.—Very considerable provision is being made by the Milan Exhibition authorities for motor cars and their component parts. A special British section is to be installed, to which the British Government have made a grant of £10,000. This being the first International Exhibition ever held in Italy, it should be of very great importance to manufacturers in this country. The King of Italy is giving every assistance to help it to success, and out of the prize-money of £4,000 which the King has presented, £400 will be awarded for the best automobile shown, under special conditions, to be published later. Motors and cycles are classed in the first section of the exhibition, viz., Land Transportation, &c., and will be on view from April 15th to June 1st. Provision is made in this section for complete motor cars, component parts of every description—rubber accessories, motor car bodies, materials for construction, motor clothing, technical and other publications, signposts, &c.

Fig. 3.—Two views of the latest type of Panhard Gear-box, showing the Three-point Suspension. A Gear-box similar to this is fitted on the new six-cylinder 50-h.p. car.

and 50-h.p. respectively. The 8-h.p. model is the well-known 3-cylinder car, and the others, with the exception of the largest chassis just described, all have 4-cylinder

THE number of British exhibitors at the Paris Salon this year are not conspicuously great. In fact, one of the few firms showing are Messrs. C. S. Rolls and Co., who are exhibiting their new 8-cylinder landaulet and their "legal limit" car.

THE 1906 LEGROS AND KNOWLES "IRIS" CARS.—PART II.

(Continued from page 1379.)

LAST week, the leading characteristics of these entirely new and well designed cars were given in the first portion of this article, and were accompanied by four excellent views of the 25-30-h.p. chassis. The photographs then reproduced showed it from the side, from above, from the front and from the back, thus enabling every portion of the mechanism to be seen in place. This week we deal with some of the more novel features in greater detail.

The Chassis.

Concerning the framework and the general arrangements of the various parts, comparatively little more need be said, because the four views that have already been given of the complete chassis render the design, as a whole, perfectly clear. Thus, in Figs. 1 and 2, it is seen that the pressed steel main-frame has straight side-members, that the full elliptic rear springs are fixed outside it, and that except for the two tubular supports for the engine, and for a light stay across from one spring-horn to the other, there are no cross-members forward

The novel form of radiator is well illustrated in Fig. 3, but a word or two by way of description may be found welcome. The diamond-shaped framework forms a kind of tank around the tubes, and the circulating pump is fixed to this framework. Owing to the fact that the vertical-finned tubes only occupy the upper portion, it is easy to remove the pump—from the front of the car—should anything go wrong with it. This is further facilitated by the use of a flexible jaw-coupling for connecting it to the engine. The pump itself is of the gear-wheel type, and there is a belt-driven fan behind the radiator.

View of the New 25-30-h.p. "Iris" Car, fitted with Standard Side-entrance Body.

of that immediately in front of the gear-box. Similarly, from Fig. 3, it is obvious that the front axle is tubular and that the ball-bearing steering-heads are of a somewhat original pattern; the axle itself has a core of ash forced tightly into place inside it, and the shape of the steering-heads permits it to pass across on a slightly lower level than usual.

The steering-gear is now of the worm and sector pattern. It is rendered very "light" in action by the use of ball-bearings, and is provided with means for taking up any end-play that may develop.

As seen in Fig. 1, the petrol tank, which has a capacity of about 12 galls., is fixed to the chassis, so that it lies beneath the front seat. Although sufficiently high up to feed the carburettor by gravity under ordinary working conditions, a pressure-feed device is connected with it as a precautionary measure. The same pressure-valve serves to make the exhaust gases feed the oil through the lubricator, and the same pressure-gauge shows whether the valve is acting properly.

The Engine.

Two views of the engine are given in Fig. 5, and in both will be noticed the wood-filled steel tubes, B, by which it is fixed in place in the chassis. These tubes pass through the upper portion of the crank-chamber, and thus enable the base casting—which merely forms an oil-tight casing—to be removed without difficulty. The bearing cups for the crank-shaft are, of course, on the underside of that shaft, being secured to the main portion of the crank-chamber. Accessibility to the interior is still further obtained by large doors on the right hand side of the engine; in our illustration one of these doors is lifted off, and laid beneath.

Each pair of cylinders is formed by one casting, and although all the valves are alongside one another on the left, the carburettor and the induction-pipe, A, are complete in themselves on the opposite side. This result is obtained by providing passages, A', for the explosive-mixture, across between the cylinders, in the castings

themselves; the exhaust-pipe-fittings alone occupy the usual position on the valve side of the engine.

Another neat feature of the engine is that the cam-shaft, complete with its ball-bearings and push-rods, is contained in an independent casting, C, that can be removed intact by taking off a few nuts. A metal-to-metal face-joint is made between the casting, C, and the main casting. Also fitted within the casting, C—at its front end—is a short cross-shaft, C', this being driven by spiral gear-wheels from the cam-shaft. The shaft, C', is

only drives the water-pump (by a direct connection) but the fan also (by a belt).

In Fig. 5, the two pipe-fittings, D and D', by which the water enters and leaves the cylinder-jackets, respectively, are clearly visible. The cool water enters around all four exhaust-valves, and leaves at the top of each jacket.

To a certain extent the lubrication and the ignition can be considered simultaneously, since the two-way switch for the latter forms a part of the lubricator-fitting

Fig. 5.—Two Views of the 1906 Legros and Knowles Petrol Engine, showing the arrangement of the Carburettor, the Induction Passages through the Cylinder-castings, the separately-detachable Cam-shaft casing, and the Inspection-doors in the side of the Crank-chamber. The specially-shaped Gear-wheels should also be noticed.

adapted to receive the horizontal spindle of the combined commutator and distributor that operates the ignition system. As shown in Fig. 2, this commutator lies in a very convenient position to the right of the engine.

The cam-shaft is driven by spur-wheels, having teeth of a special shape, from the metal pinion, C³, on the crank-shaft. Interposed between the pinion, C³, and the spur-wheel, C⁴ (on the cam-shaft), is the fibre-wheel, C², and this wheel not only serves to render the gearing silent, but it also lies in line with the circulating pump. The teeth are unusually wide on the wheel, C², and are unusually far apart on the metal wheels, C³ and C⁴, and they thus compensate for the inferior strength of the non-metallic material. The further ingenuity of the designers is displayed by the fact that the wheel, C², not

on the dashboard. When the switch is in its neutral position, the oil-feed, through the sight-feed glass, to the crank-chamber is interrupted simultaneously with the current from either battery, but in either of the "on" positions the oil is free to flow. One battery or the other is then rendered operative for the ignition and for the carriage lamps, while a specially arranged dynamo is automatically made to recharge the idle battery. A single trembler coil feeds all four ignition-plugs, the glass-cased distributor (already mentioned), connecting it alternately with each plug in turn. When the switch is made to "change over" from one battery to another, the direction in which the current flows through the primary circuit is reversed, thus rendering the platinum contacts less liable to require attention through "pitting" at the positive pole.

(To be continued.)

THE 1906 AUSTIN PETROL CARS.

So great has been the success of the cars for which Mr. H. Austin has been responsible, as manager for the Wolseley Company, and so well known is he and his work in all motoring circles, that our readers—and all those who take an interest in substantial and serviceable touring cars—will naturally be anxious to obtain particulars of the new cars which bear his own name. At present, he is busily engaged in completing the equipment and organisation of his extensive works at Northfield, where we hope shortly to be able to pay him a visit in order to thoroughly acquaint ourselves with the "Austin" cars. For

the time being, we are only permitted to state that the first models to be turned out by him will be a live-axle car having a 15-20-h.p. engine, and a 25-30-h.p. vehicle, which can either be supplied with side chains or a shaft drive. Everything will be ready very shortly to build these cars on a large scale, and already excellent progress has been made with a view to early delivery next year. Mr. Austin has always been such an ardent advocate of simple design combined with strong construction, and has had such a unique experience in the manufacture of reliable cars, that it is safe to predict great things for those which are to be made in his own factory.

HIGH-TENSION MAGNETO IGNITION.—PART XVI.

THE GIANOLI SYSTEM.

*(Continued from page 1387).***The Armature**

EXCEPT for the fact that the armature carries the contact-breaker on the back of one of its end-plates, there is nothing which at first sight distinguishes its con-

would be the case if the laminæ were continued to the circumference in the usual way. This form of construction also gives considerable mechanical rigidity to the armature.

The ends of the core are secured to ordinary brass end-plates, B^s, which carry the halves of the armature-spindle, B and B'. In the present type, the construction

FIG. 4.—The Gianoli High-Tension Magneto.—Sectional drawings showing the construction of the machine. The manner in which the high-tension current is led from the Secondary Winding, D, to the Contact, D², is clearly shown in these views.

struction from other armatures of this type, although in detail it has actually many peculiarities. The centre part of the core, A, is laminated in the usual way, but instead of the laminæ extending to the circumference, they are cut off short, and the side-plates, A¹—which, as usual, are solid pieces of metal secured in place by screws—extend throughout the length of the armature. Cast in position on these side-plates, A¹, are the small pole-pieces, A² (Figs. 4 and 5), used for operating the automatic contact-breaker, C³, and it is because these pole-pieces must be readily magnetised by the armature current, that the side-plates, A¹, are attached in the manner described; it is by so doing that this particular magnetic circuit is rendered less reluctant to the passage of the lines of force, than

of this detail follows the usual practice of screwing and riveting the ends of the steel spindles directly into the brass plates. An improvement will be introduced in next year's model, however, in order to make this joint stronger, and the spindles will be forced into long brass sleeves, cast solid with the end plates. The latter method of construction has, of course, only been rendered possible by the adoption of ball bearings, because otherwise the brass sleeves themselves would be running in contact with the plain bearing surfaces.

Both the primary and secondary coils are wound on the armature core; the primary winding, C, being adjacent to the iron, and the secondary winding, D, being wound over the primary and connected to it (Fig. 10).

(To be continued.)

FIG. 5.—The Gianoli High-Tension Magneto.—Detailed views showing the construction of the automatic Contact-breaker, which is one of the principal features of this system. The Contact-breaker acts, in this Magneto, like the trembler of an ordinary trembler-coil.

VISITORS to the Show, who know what they especially wish to see, have but to glance in this index for the number of the stall which they require, and to use the plan on page 1428 as a guide to its position. Our own stand is on the ground floor in the south-west corner of the main hall, and we hope that our readers will not

hesitate to apply there for information on any matter in which we can assist them. We would also draw attention to the fact that most of the important cars exhibited are being, or have been, fully illustrated and described in our columns, and most back numbers containing such references will be available at the Show.

OLYMPIA EXHIBITION, 1905-6.

Buyers' Guide to Exhibited Cars classified by Number of Cylinders and Price.

NOTE.—In certain cases the information available is so meagre that we have not felt justified in including such vehicles in our otherwise very complete list of reference.

Leading Characteristics—
Drive.—S = Propeller Shaft; C = Single Chain; CC = Side Chains.
Engine—
Type.—D = Diagonal; V = Vertical; H = Horizontal.
Cylinder Capacity.—Assuming that 5,000 cubic inches were equivalent to 1 horse power, the figures in this column denote the powers of the engines if 5,000 cubic inches suction = 1 h.p.
Ignition.—b = Battery; m = H. T. Magneto; M = Low-tension magneto; a = Automatic timing.
Fuel Feed.—p = Pressure; g = Gravity.
Control.—G = Automatic Governor; H = Hand Control.

Transmission—
Clutch.—lc = Leather Faced Cone; mc = Metal Cone; mt = Multiple Disc; sd = Single Disc; ca = Expanding; sc = Scroll; dc = Double Cone (leather and metal).
hy = Hydraulic.
Change Speed Gear.—S = Sliding Spur; E = Epicyclic; U = Unusual.

Bearings—
P = Plain; B = Ball; R = Roller.

Dimensions—
Wheel Base.—Shortest standard model given where different lengths made.
Tyres.—f denotes that the front wheels are of different size.

THE MIDDLETON PNEUMATIC HUB.

AMONG the numerous inventions for rendering solid-tired wheels more resilient, the majority, at any rate of those which have reached a practical stage, have been purely mechanical, relying entirely on steel springs to provide the elastic medium between the wheel proper and the axle supporting it. The Middleton hub, how-

The inside of the housing, A, is hollowed out to form a concave recess for the accommodation of the annular pneumatic cushion, C, which is made of slightly larger diameter, and has to be "sprung" into position in consequence. Metal flanges fit closely against the sides and base of the cushion, as shown in Fig. 4, and help to prevent it from spreading under the load. The cushion and its flanges are secured in place by the plate, A³, which is flush with the casting, A.

Through the centre of this cushion passes the hub, B, which is of quite ordinary construction and can be made to suit either a live-axle or chain-driven car. The hub itself carries a large flange, B¹, which is solid with it, and on this flange are a set of studs, B², which pass through slots, A², in the housing. When the hub-member, B, is in place, another flange, B³, is secured on the other side of the wheel by means of nuts, which screw on to the studs, B². The studs themselves also form distance-pieces, and thus prevent the flanges, B¹ and B², from being tightened up against the housing, A. About four-thousandths of an inch total clearance is allowed between these members in order to prevent seizing. It is, of course, the

Fig. 1.—The Middleton Pneumatic Hub.—View of a Car fitted with these hubs and shod with solid rubber tyres. The neatness and small space occupied by this device is apparent from this photograph.

ever, belongs to a class which is at present in the minority, for the resilience of this wheel is obtained from a pneumatic cushion surrounding the hub in much the same way that a pneumatic tyre surrounds the felloe.

The simplicity of this arrangement is not the least of its desirable features, and the substitution of a pneumatic cushion for metallic springs, also, will doubtless be regarded with favour by many who have cause to appreciate the shock-absorbing qualities of compressed air. A pneumatic tyre *inside* the wheel is, of course, in a very different condition, dynamically, from what it is when it forms the periphery and comes in direct contact with the road. While in the interior, it cannot, for instance, "swallow" the stones and other small obstacles which constantly oppose it, but, on the other hand, there appears to be no reason why many of the inherent advantages of pneumatic tyres should not be retained, although the difficulties of doing so are considerably greater than is apparent at first sight. There is, however, the immunity from punctures, and the increased life which such an arrangement affords, and these advantages, in themselves, not only remove the most important drawbacks to pneumatic tyres, but offer some compensation for such reductions in resilience as this method of construction entails.

The Middleton Pneumatic Hub, which has been put on the market by the Middleton Pneumatic Hub Syndicate, is of very simple construction, as is evident from our photographs, which show it fitted to a car (Fig. 1), and also separately (Figs. 2 and 3). There is but little difference in appearance between it and any ordinary motor car wheel, for it is very compact and also permits the use of wood spokes, which is rather the exception than the rule in resilient wheels. The wheel proper is, in fact, built up on very much the same lines as an artillery wheel, except that the housing, A, is of much larger dimensions and has the spoke bases independently fixed into sockets, A¹, cast to receive them.

flanges, B¹ and B³, which have to withstand all the side strains which are imposed on the wheel.

The drive from the engine, which comes first upon the hub-member, B, is transmitted through the studs, B², to the housing, A, and then to the wheel proper. In future models some soft rubber or other resilient substance will, we understand, surround these studs in order to cushion their action against the walls of the slots, A².

Fig. 2.—The Middleton Pneumatic Hub.—Closer view of a wheel, fitted with the device, showing the Pneumatic Cushion, C, in place.

Fig. 3.—The Middleton Hub.—Views of the component parts separately.

For the purpose of inflating the cushion an ordinary tyre-valve, C¹, is provided, and this projects through a hole in the casting, A, so that it is accessible from the

Fig. 4.—The Middleton Hub.—Sectional drawing showing the construction of the Hub.

outside. The pressure to which the cushion is blown up depends of course on the weight of the car, but it is generally somewhere between 120 to 200 lbs. per square inch, and is always sufficient to prevent anything but a very slight eccentricity of the hub under its working load. The cushion is made on the same principle as an ordinary single tube pneumatic tyre, and its walls are particularly stiff in order to prevent them from spreading over their metal flanges, C². This spreading was one of the difficulties encountered in the early experiments with this device. Under the present system, the walls of the cushion are thoroughly well supported, externally, for the same reason, and it is now practically impossible for any "bellows" action to take place in them, even under the most severe loads; nor can much deflection occur, either in the base or periphery of the cushion, on account of the very large areas which are in contact.

Creeping, which would speedily ruin the valve-stem, C¹, is prevented by the very simple expedient of allowing the flanges, B¹, to be a free fit about the hub, so that the latter can turn independently of them until the driving-pins, B², touch the sides of their slots.

Table of Reference Letters for the Middleton Pneumatic Hub Illustrations.

B	Hub.	C ¹	Valve for inflating C.
B ¹	Flange fixed on B.	C ²	Metal side-flanges for C.

THE interests of heavy traffic are to be represented before the Royal Commission by the Motor Van and Wagon Users' Association, who have arranged for two of their members to be heard by the Commission next week. The heads of the evidence which the members in question will furnish refer to licensing, in regard to which they will make a proposal that each heavy car should be licensed at a cost of 5s. per ton on the combined registered axle weight, and suggest that the sum so obtained should be paid into a central fund, which fund is to be disbursed for the maintenance of roads of a prescribed standard of strength. As regards the wheel and tyre dimensions, the Association are opposed to any alterations for the present, no fair trial, they think, having been given to the existing regulations and users having been put to considerable expense in complying with the Local Government Board's order in this respect.

The representatives will urge the abolition of the speed limit in regard to vehicles shod with resilient tyres, on which point we trust they will be successful, as success will mean the removal of the present 12-mile limit for motor 'buses. A more questionable demand which the Association is to make by its representatives before the Commission, is that any hauler or user of heavy traction vehicles should have the right to have roads opened up to demonstrate whether they are suitably constructed or not, provided he pays the cost of such undertakings. The Association seem to forget that the general application of this principle, if permitted, would be to cause a very serious amount of annoyance to other road users. The Association will further urge that the licensing of omnibuses should rest with the County Councils and Borough Councils, with a right of appeal to the Local Government Board.

FURTHER evidence of the feeling amongst the inhabitants of Andover, in regard to the "Handover" Bench, and the associated police trap which provides it with victims, is furnished by the fact that the Town Clerk of Andover has been writing to the papers, pointing out what most people are aware of, that the townspeople of Andover have had nothing at all to do with the campaign, and that the police trap has been organised by the County Police, who are under the county authority and are not controlled by the town. It is a comic opera comment on our institutions when a reactionary pig-headed Bench and a subversive constabulary blockade a country town and successfully keep out of it guests which the townspeople are only too anxious to welcome.

AT OLYMPIA.—One of the luxurious 1906 White Steam Cars, fitted with a removable Brougham Top, which has an extended Canopy carried forward to meet the wind screen in front, and so afford a large amount of protection to the driver.

Driving Examinations.—Additional particulars are issued of the Automobile Club examinations for driving and mechanical proficiency certificates. The club has already held several examinations in London and another is to be held at 119, Piccadilly, London, W., on November 20th, and continued each day up to and including the 24th. These examinations have been primarily arranged to meet the convenience of any candidate from the provinces who may be in London during the Olympia Show week. Already several examinations have been held in the provinces, and in addition to the following list further provincial examinations will be arranged for the North of England and Scotland early in the New Year:—

November 28th, Antelope Hotel, Poole, Dorset; November 29th, Castle Hotel, Southsea; November 30th, Warne's Hotel, Worthing; December 1st, Fleur-de-Lis Hotel, Canterbury; December 5th, Mulliner's Carriage Building Company, Northampton; December 6th, Suffolk Hotel, Bury St. Edmunds; December 7th, Maid's Head Hotel, Norwich; December 8th, Saracen's Head Hotel, Lincoln.

ARBITRATION is one of the new developments in connection with the Motor

OLYMPIA.—Front view of the Delaunay Belle, showing the very neat eccentric-shaped which is one of the most distinctive features of these well-made vehicles.

Union, who have taken the important step of undertaking to arrange for the appointment of arbitrators in disputes. By this means many differences between automobilists and dealers will probably be dealt with in a much more satisfactory manner than by taking the disputes into the law courts. In a case which has arisen between a member of the Union, at Swindon, and a motor car dealer, at Epsom, the Union, regarding the case as a proper one in which they can act, have nominated Mr. Walter Bourke, M.I.C.E., of Maidenhead, as arbitrator.

AT OLYMPIA.—The new 20-25-h.p. Mercedes Car, modelled on the lines of the popular 18-28-h.p. Chassis which it supersedes this year.

WE notice that a morning illustrated paper has apparently attempted to adapt our suggestion about the London County Council arms, by producing an illustration of an imaginary shield more or less on the same lines. Alas, our contemporary has made a terrible hash of its heraldry, and altogether we are quite thankful that the paper in question omitted to make any acknowledgment to THE AUTOMOTOR JOURNAL.

IN recognition of the public-spirited action of Mr. Frederic Coleman in recently appealing against his conviction at Colchester, for driving at a speed dangerous to the public, the Motor Union

AT OLYMPIA.—One of the latest 24-40-h.p. Fiat Cars, fitted with handsome Limousine Landaulette body.

THE statistics of motor vehicles for the County of Essex, from January 1st to September 30th, have been returned by the registrar. The total amount received in fees is £2,118 3s., from which, after deducting expenses of administration, £472 17s. 8d., there is a nice little balance to the benefit of the county of £1,645 5s. 4d.

LORD WINDSOR, whose action in refusing automobiles admission to the parks last summer was a subject of much discussion in the Press, has been promoted to an Earldom, and is now Earl of Plymouth. A sprightly contemporary, which is still angry with his Lordship's action, suggests that the Earldom of Barparks would have been an even more appropriate promotion—it would certainly have a thoroughly Thackerayan sound.

AT OLYMPIA.—English 'Buses for Foreign Service.—The Società Romana Tramways Omnibus, constructed by Messrs Thornycroft and Co., on the same lines as vehicles exhibited by them at the Show.

have made a contribution of 15 guineas towards Mr. Coleman's legal expenses.

MR. R. L. JEFFERSON, who left Coventry some weeks ago to travel by motor car to Constantinople, arrived safely at his destination last week. This is the first occasion of a motor car having crossed Turkey.

AT OLYMPIA.—The Harper Car.—A modified form of Cadillac Car re-designed and constructed with Cadillac machinery by the Harper Motor Co. Its special feature is its system of control, by which each speed is brought into action by a foot-pedal, the left foot being used solely for this purpose, and the right foot being, therefore, free to operate the brake.

THE Cadillac Automobile Company of Detroit, U.S.A., have changed their name to the Cadillac Motor Car Company, and increased their capital from 300,000 dollars to 1,500,000 dollars. At the same time they have amalgamated with the Leland and Faulconer Manufacturing Company. This latter concern has hitherto always made the Cadillac engines, and the combination, therefore, should be of considerable importance to both companies.

E.C., and give the fullest particulars and details in clear and succinct language.

THE Wolseley Motor Car Company have forwarded a donation of £50 to the Legislation Fund of the Joint Committee of the Automobile Club and the Motor Union. This Fund now amounts to £3,500.

A PLEASING example of police methods is provided by an occurrence which took place recently on the Portsmouth Road. A steam roller was at work over a considerable stretch of the highway, rolling in freshly-deposited flints, and, of course, all automobiles which had to negotiate this stretch of "prepared track" could only do so at a walking pace. Recognising the characteristics of ordinary human nature with a subtlety worthy only of Russian *Agents provocateurs*, the police laid a trap a little on the London side of the steam roller, on a perfectly open stretch of country where no one was about. There is a contemptible element of ingenious meanness about this that positively thrills one.

AT OLYMPIA.—An up-to-date Touring Car.—View of one of the new 18-h.p. White Steam Vehicles, fitted with cape cart hood and roomy side entrance body. A description of the latest chassis has already appeared in our columns.

THE Automobile Association inform us that the cyclist patrols on the Portsmouth Road are being now directed and controlled by Mr. Thring Robinson, a member of the Executive Committee. In addition the Association are arranging to establish patrols on any roads within thirty miles of Charing Cross, in regard to which they shall receive information that such patrols are advisable. Anyone, therefore, who detects a previously undiscovered or newly organised "motor car trap" within this distance of London should write to the Automobile Association at 18, Fleet Street,

A new design in motor car body work, which has been placed on the market in Germany by Messrs. Dick and Kirschten, of Offenbach.a.M.

supporter of the Mercedes make of car. Mr. Dinsmore was the son of Mr. W. B. Dinsmore, the founder of the Adams Express Company.

By the sudden death in New York last week of Mr. Clarence Gray Dinsmore, at the age of fifty-eight, the automobile world has lost a figure familiar at practically every race meeting of any consequence either on the Continent or in America. Mr. Dinsmore was the official delegate of the Automobile Club of America at the international meetings of the recognised clubs, and was a particular

AT OLYMPIA.—Two De Dion Commercial Vehicles.—An 8-h.p. Delivery Van and a 12-h.p. Lorry. The smaller vehicle has a single-cylinder engine, while the larger engine is of the twin-cylinder type.

A MOTOR PATROL BOAT.—Messrs. S. F. Edge have just supplied a foreign Government with this boat for coastguard use in the prevention of smuggling. It is a 35-ft. craft, built by Saunders, and has a 70-h.p. Yarrow-Napier Engine, of which the normal speed is only 800 revs. per min. The specified speed of the boat is 15½ knots.

AERONAUTICS.

An Aeronautical Gordon-Bennett.—Mr. James Gordon-Bennett, as announced at the Aero Club of France recently by the Comte de la Vaulx, has decided on dedicating a work of art, to cost 25,000 francs, to the purpose of creating a great international aeronautic contest on somewhat similar lines to those in accordance with which the Gordon-Bennett automobile race was originally organised. The trophy will be competed for the first time when the first competition of the Aeronautical Federation takes place in Berlin. The rules are now being drawn up, and it is proposed that the Aeronautical Gordon-Bennett should be competed for annually. We think there can be little doubt as to who will win the first competition, if they condescend to compete, but no doubt the existence of a trophy of the kind will have a considerable effect in stimulating enterprise in this direction.

A MODEL of the "Lebaudy" airship, which has recently completed very successful trials, will be on view at the Continental Tyre Company's Stand No. 256 at the Olympia Show. The fabric of the gas-vessel of the airship was supplied by their Hanover house, and has been an important factor in the successful results obtained.

A SERIOUS fire took place in Birmingham last week on the premises of the Dunlop Rubber Company, when considerable damage was done to the stock and buildings. In addition, the fire spread to the premises of the Birmingham Aluminium Castings Company.

DURING the hearing of a motor car case at Chertsey recently, a constable mentioned that a lady in one of the cars he stopped inquired where the police were stationed. "I told her," he said, "in the hedges, and she then wanted to know 'if there were any more hedges.'" The fair motorist was evidently not a careful reader of the automobile Press and not very observant of English landscape.

Catalogues.

Thornycroft Touring Cars. John I. Thornycroft and Company, Limited, Chiswick.

A COVENTRY medical practitioner, in an interesting communication to the Swift Motor Company, places the motor car in a very favourable light compared with the cost of horses' keep. He states, "I find the cost of petrol and oil for July, August, and September comes to £5 16s. 6d., as compared with £14, for corn, hay, and straw for a like period, for two horses." The above supplies a practical object lesson to doctors who are still wavering between two opinions, the retention of their horses, or the adoption of a motor car.

A Wolseley Light Delivery Van.—This handy little car has become a familiar sight in the West-End of London, and it represents a type of commercial vehicle which deserves to become very popular on account of its handiness in traffic. The Chassis is the same as that of the famous 6-h.p. Wolseley Pleasure Car.

CLUBS AND ASSOCIATIONS.

Yorkshire A.C.—The Club opened its winter season last week with a social evening at the headquarters, the Great Northern Hotel, Leeds.

Mr. E. H. Hepper presided, and in the course of a few remarks said that the view that anti-motorists held, that motorists were having their day, and that very shortly their time would have gone by, did not appeal to him. He felt assured that at the end of the sittings of the Royal Commission they would find that motorists would have more latitude than in the past.

During the evening an illuminated address was presented to Mr. H. R. Kirk, one of the club's vice-presidents, as a memento of the occasion of the first club run of the season to Windermere, when he entertained the members of the club and their friends. In making the presentation, Mr. Hepper said that Mr. Kirk was essentially a practical motorist. In his time he had had about twelve cars of different makes. He was not only a vice-president, but he brought a practical value to the office of vice-president. He had gone beyond the mere name, and had done a great deal for the benefit of the Yorkshire Club and for motoring, not only on the road, but also on the water.

Mr. Kirk, who met with a very hearty reception, briefly thanked the members.

A silver table lamp with electric fittings was presented to Mr. Hey, the hon. treasurer of the club, in commemoration of his recent marriage.

A capital programme of songs, given by a number of friends, enlivened the evening's proceedings.

Essex Automobile Club.—A meeting of the provisional committee appointed by the Motor Union to form an automobile club for the county of Essex, was held on Wednesday last, at the Great Eastern Hotel, Bishopsgate Street.

Mr. Burnett Tabrum, J.P., was elected to the chair, and Mr. E. C. Tijou was appointed hon. secretary, *pro tem.* A code of rules was drawn up, and arrangements made for a general meeting of the automobilists to be held on Wednesday, November 29th, at the same venue, to formally establish the club. Information on all points may be had upon application to the Secretary of the Motor Union, 16, Down Street, Piccadilly, W., or to Mr. E. C. Tijou, 3-4, Fowkes Buildings, Great Tower Street, E.C.

A list of the members of the provisional committee was given by us in our issue of October 28th.

AT OLYMPIA.—"Sylvia."—A 20-foot motor-boat, engined by Messrs. Thornycroft with one of their 6-h.p. Marine Sets. This was one of the Thornycroft "fleet" at the Reliability Trials this year.

Hartlepool's A.C.—At the first annual dinner of the club, which took place last week at the Grand Hotel, West Hartlepool, Mr. C. E. Smith, one of the oldest automobilists in the district, presided over a big muster of members and guests. The speeches were short, in order to allow full scope to an excellent musical programme which was provided.

The toast of the evening, success to the club, was in the hands of Mr. H. M. McLean, who mentioned that the club had only been in existence two years, and now had a membership of forty.

The chairman, during a much appreciated speech in reply, in mentioning the benefits which had accrued from the introduction of mechanical vehicles, instanced Coventry, which he said was practically a dead town until it developed the cycle and motor industries.

Brighton and District Automobile Association.—Under this title a new Association has been formed at Brighton for the purpose of dealing with matters vitally affecting the interests of automobilists in the district. The rules are modelled upon those of the Automobile Association, the objects in the main being the same. A defence fund is to be created for the purpose of defraying the legal costs of members attacked. Mr. Blackburn, the Secretary, is organising an automobile exhibition in Brighton to take place in the Dome and Corn Exchange next February. The whole of the gate money at this exhibition will be presented to the Association to form the nucleus of the defence fund. As Mr. Blackburn a few years ago promoted a similar exhibition which resulted in the Hull Royal Infirmary benefiting to the extent of £480, the Association have a pleasant prospect before them of being able to bank a substantial amount as the result of Mr. Blackburn's fresh efforts. Lord Turnour has consented to be President of the Association, and the first members of the Committee are Captain W. N. L. Davidson and Messrs. Herbert Handley, Alfred Gregory (Hove), Henry White, J. H. Thompson, M. Holford-Strevens, C. Duval, C. A. Scott, A. Chopping, J. A. Lereculey, Henry Rogers, Horace North, Jos. Snuggs, R. F. Round and C. B. Pemberton. The Secretary is Mr. W. Blackburn, Hon. Treasurer, Mr. Walter Tilley, and the Gloucester Hotel has been selected as headquarters. The subscription for car owners is 2 guineas, for motor cycle owners 1 guinea, hotel proprietors 1 guinea, and boarding-house proprietors 10s. 6d. These subscriptions include the free use of the North Brighton Motor Garage, Park Crescent Place, under certain conditions.

Photo by Argent Archer.

Last week we gave a few particulars in regard to the new Motor Academy, which has been installed at Boundary Road, Notting Hill. Above we give a photograph of some cars in the driving school. In this, some of the obstacles, in the form of dummy dogs, &c., will be noticed; the white lines are for the purpose of enabling drivers to keep within certain points under specific driving conditions.

RACES, RECORDS, AND TRIALS.

The "Targa" Florio.—The running of this race has been now officially fixed to take place on May 5th next year, over a 500 to 700 kilometre course in Sicily. Six cars of the same make only may be entered, of which three may be engaged by the manufacturer, and three by private owners. But failing entries from the manufacturer, an equivalent number may be entered by private owners so as not to exceed the total of six. Entries will close twenty days prior to the race for manufacturers, and fifteen days for private owners. The latest model of each car will have preference over previous years' types in acceptance of entries.

French Tyre Trials.—The rules have been issued by the A.C. de France governing their Tyre Trials, which are to be held next year. They are only open to makers of wheels and tyres. Each maker may enter a maximum of four cars, the four tyres on each car to be of one pattern. The entry fee is 3,000 francs up to February 15, and double fees up to May 15. The distance of the test will be over 1,000 to 1,500 kilometres, either in one or two stages. The weight of the chassis of each car is to be 1,000 kilos. minimum, 1,200 kilos. maximum, this weight including the carriage body and practically everything except tools. In addition each car must carry 400 kilos. of ballast. Each vehicle will be allowed four inner tubes for re-changing, and all repairs, &c., will be carefully noted throughout the run. There will be two classes, viz. :—

1. Pneumatic tyres, properly so called, without any other elastic material in them except gases under pressure contained in some sort of envelope or case between the rim and the surface on which it runs.

2. Tyres of all other systems, including solid rubber tyres and spring tyres, or a combination of the two principles. Entrants in this class must declare beforehand what parts it may be desired to change, and how often, during the test.

The winner will be the car covering the specified distance in the shortest time, subject to his presenting his car at the finish to the officials and complying (1) with the necessary conditions under the rules as regards weight, (2) with the wheels and the tyres and other necessary parts in proper condition, and in position with seals intact as before the start.

Flying Kilometre Record.—On Monday last, on the Salon-Arles Road, near Ostend, Frederic Dufaux, on the 4-cylinder 150-h.p. Swiss-built Dufaux racing car (Michelin tyres), put up a new official Continental record for the flying kilometre, his time being 23s., equal to 156.52 kiloms. per hour. This beats Rigolly's record at Dourdan by $\frac{2}{3}$ s. *Unofficially* Baras has been timed with 21 $\frac{2}{3}$ s. in 1904 for the distance. The world's record of 21 $\frac{2}{3}$ s. is, therefore, still with Clifford Earp.

HEMERY having made proper explanations and apologies in connection with the episodes which occurred in Italy during the Brescia week, the Italian Automobile Club have decided to cancel his disqualification recently announced. Hemery is, therefore, now again free to take part in international racing.

MONT CENIS hill-climb, next year, will take place at the end of June, and Brescia week from August 27th to September 2nd, this meeting winding up with the Florio Cup on September 2nd.

MOTOR CYCLING.

THE "Tour de France" for motor cycles and voiturettes organised by *Les Sports* is announced to take place from May 13th to 24th next. The three classes are light motor bicycles, $\frac{1}{3}$ rd-litre motor bicycles and voiturettes. The stages are :—May 13th, Paris-Tours; May 14th, Tours-Bordeaux; May 15th, Bordeaux-Toulouse; May 16th, Toulouse-Nîmes; May 17th, Nîmes-Marseilles; May 18th, Marseilles-Gap; May 19th, Gap-Saint Etienne; May 20th, Saint Etienne-Besançon; May 21st, Besançon-Nancy; May 22nd, Nancy-Reims; May 23rd, Reims-Amiens; May 24th (Ascension), Amiens-Paris.

COMMERCIAL POINTS.

MR. E. H. LANCASTER is giving away, at the Clement stand, No. 59, during the Olympia Show, Clement horse-power indicators, by the means of which the horse power of any engine can be ascertained.

THE Sirdar Rubber Company, Limited, advise us that owing to their increased output, they have not found it necessary to raise the price of their tyres, either pneumatic or solid, in consequence of the rise in rubber. We also learn that the Vanguard omnibus, running from London to Croydon, Redhill, and Brighton is fitted with Royal Sirdar rubber tyres.

MESSRS. TEMPLETON BROS., of Glasgow, advise us that they have fitted up extensive premises at 535, Sauchiehall Street, nearly opposite the Grand Hotel at Charing Cross, as Motor Show-rooms and Garage.

MR. JOHN HARGREAVES has just secured a 29-h.p. Hotchkiss car with a double landaulette body, and Lady Idina Brassey has purchased a smart little 10-h.p. Vulcan car, both of these being arranged through the medium of the agents, the London and Parisian Motor Company, Limited.

WITH reference to our article on the latest Gratz Speed Indicator, which appeared last week, the Gratz Patents and Engineering Syndicate write us that the British Electric Equipment Company have not been granted the sole agency for these instruments.

WITH reference to Mr. R. L. Jefferson's drive on a car from Coventry to Constantinople, the United Motor Industries, Ltd., advise us that the car was fitted with a pair of their Model R "Castle" lamps, "Castle" tail lamp, "Castle" porcelain plugs, "Castle" double-coil horn, "Castle" induction coil, and "D" lubricating oil.

MESSRS. SHIPPEY BROTHERS inform us that they have been appointed sole agents for England and the Colonies for the sale of the new "Michigan" Petromobile Cars, and that the first shipment of 12-h.p. and 16-h.p. cars have arrived in England, and are ready for trial runs.

MESSRS. A. DARRACQ AND CO., LIMITED, advise us that their luck in the ballot for space at the Olympia Show did not give them the opportunity of securing a stand in the main building. But they have endeavoured to make up by special means to get their position, 125, in the Annexe, known. A full range of 1906 model Darracqs will be on view, and in addition Hemery's car, with which he secured the Ardennes Circuit and the Vanderbilt Cup Races, will be staged.

MESSRS. RENNIE AND PROSSER, LIMITED, of Mitchell Street, Glasgow, have been appointed sole agents for Scotland for Panhard and Levassor cars, under licence from Mr. Harvey du Cros, in addition to being appointed official repairers in Scotland to the firm. In view of the methods adopted by Messrs. Rennie and Prosser, Mr. Du Cros will not, we learn, think it necessary to send his Panhard travelling repair-shop to Scotland. They have also been appointed sole agents for Mercedes cars for Scotland with the exception of three counties.

WE learn that Messrs. Clarkson, Limited, have received orders for fifteen more of their steam omnibuses for running in London. It will be remembered, under this system, paraffin instead of petrol is used for fuel.

COMPANY DOINGS.

Argyll Motors, Limited.—Mr. W. Alexander Smith, presided at the annual meeting of Argyll Motors, Limited, held in Glasgow last week. In his remarks to the shareholders, he stated that the profits of last year, which enabled them to pay an ordinary dividend of 10 per cent. was the more satisfactory as every shilling had been earned in the old Hozier works. The new capital had, as a matter of fact, been a burden from which the company had derived no practical benefit up to the date to which the accounts referred. It would be gratifying to the shareholders to know that everything had been debited that could be possibly charged in the accounts, in respect to construction and application against revenue. Their accounts, in fact, had been treated most drastically in this respect, including the depreciation which had been written off. £3,000 had been placed to special reserve for the Preference shareholders, and £4,000 had been placed to general reserve.

With respect to the new works at Alexandria, these were now a busy hive of industry. They had a large proportion of machinery working, turning out material for the 1906 season. He was confirmed in his opinion that with all their advantages in the new works they were in a position to lick the world, and it would be no fault of theirs if they did not take full advantage of the situation. Their prospects were of the best. They had on their books orders to the value of from £500,000 to £600,000. Last year they turned out exactly, to a car, twice as many as they had done the two previous years, and seven times their trade of three years ago, and he hoped that next year they would again double their output. The whole of this success he claimed was due alone to the real merits of the Argyll car.

The accounts and the recommendation of the directors were unanimously passed, with a cordial vote of thanks to all those concerned in the management.

Daimler Motor Company (1904), Limited.—All-round Reduction in Prices.—At the meeting of the shareholders of the Company last week in London, presided over by Sir Edward G. Jenkinson, K.C.B., chairman of the Company, the accounts and recommendations of the directors in regard to dividends, as reported in our last issue, were unanimously approved.

The chairman, during a very long and clear speech, reviewed the affairs of the Company from the first year after the reconstruction, explaining what had been done since that time. By way of showing the progress made, he pointed to the gross and net profits for the previous year, and for the past year, as follows:—

	Gross.		Net.
1903-4 ...	£24,760	...	£7,334
1904-5 ...	£106,313	...	£83,167

The secret of the success they had had, he attributed to the fact that they were able, with their capital in hand to do in the past year what they had never been able to do before, viz., to manufacture cars for sale in advance of the season, with complete confidence that they would have no difficulty in selling them when the time came. They were able also to spend money on the extension of their works and the purchase of machinery, thereby increasing the output. The results were seen in the accounts presented. Up to September 30th, 1904, little progress had been made in actual output, but the past year had seen a great stride forward. Their floor space was increased by 75 per cent. over that of 1903, and when their extensions were complete, about December, the increase would be 240 per cent. The value of buildings in August, 1905, had increased 98 per cent. over the value in August, 1901, and the buildings being erected, when completed in December, would increase that value to 273 per cent. Plant and machinery had increased by 28 per cent., from September, 1904, to August, 1905, and the increase by the end of December over September, 1904, would be 82 per cent., and over September, 1901, 105 per cent. By these extensions they would be enabled to quadruple the output capacity of their works. Their sales receipts were 120 per cent. better than in 1904, and 305 per cent. better than in 1901.

In mentioning the latest honour which had been bestowed upon the company by His Majesty the King by an order for one of the 35-h.p. cars, he stated that this was the model which, throughout the past season, had achieved such phenomenal success in various hill-climbing and speed contests. It was the seventh car which the company had had the honour of constructing for His Majesty. The Prince and Princess of Wales had also given them orders for cars, the former for a 35-h.p. car and the latter for a 28-h.p. landaulette.

The results of the contests in which they had competed had demonstrated the uniformity in running of their cars, as almost invariably their competing cars finished within a few seconds of each other.

Coming to the 1906 type, he mentioned that there would not be any alterations of any moment. They would have nine distinct types for sale. These cars would be of three lengths, viz., 8 ft. 6 in., 10 ft., and 11 ft. wheel-base respectively, and each of these three lengths would be fitted with one of three sizes of engines, viz., 28-h.p., 30-h.p., and 35-h.p., thus making nine types. Mr. Martin, their engineer, and his staff had succeeded in making a large majority of parts interchangeable for these nine types of cars, which would help their customers very materially in being able to obtain new parts without difficulty.

The chairman also announced the very considerable reduction in the future prices of the company's cars. The 28-h.p. chassis, which was £700 in 1905, is to be £590. The 30-h.p. chassis is to be reduced from £825 to £690, the 28-h.p. chassis from £800 to £690, and the 30-h.p. complete car from £1,010 to £875. By thus reducing the price of the cars, they would be in a position to compete successfully with the manufacturers of large cars, chiefly French, and would, in addition, attract many more customers.

The company, he announced, had decided to embark on a new policy by trying the *depôt* system, in the country, and had decided to open two *depôts* in Nottingham and Manchester, instead of dealing through agents. These *depôts* were well equipped with modern machine tools and a qualified staff of mechanics in order that all their repairs might be executed at moderate charges. He was glad to say that during the last three years English manufacturers had come to the front, and on the whole were forging ahead more rapidly, he thought, than the foreigners, but this was mainly in low priced cars. In the trade in large, high priced cars such as those manufactured by their company, the foreigner was more than holding his own, a fact due to the home trade being unequal to the demand in this class of car. They, therefore, must not be content with only lowering their prices, but they must also increase their output. At present their energies were concentrated on the manufacture of large cars, because they could sell as many of these as they could turn out, but they were quite prepared to undertake other work should there be a falling-off in the sale of the large cars. They were ready with types of light cars, delivery vans, and public service vans, and luries.

The chairman later pointed out that it was necessary to pay for the extensions in the works now in progress which were approaching completion as well as to provide a sufficient working capital. The Board had therefore decided to make an issue of 20,092 ordinary and 30,800 preference shares, which would be offered to the shareholders *pro rata* at a premium of 7s. 6d. per share, which was equivalent to giving the shareholders, in addition to the dividends already recommended, a handsome bonus, as the market premium was above the 7s. 6d., at which premium the shares were to be issued to the shareholders. Before concluding, the chairman stated the directors wished to acknowledge, in the success which had attended the working of the business, the services rendered by the managers, the secretary, and the staff.

In conclusion he said that although they had had a remarkably prosperous year, they must be prepared for all contingencies and must take care always to have a provision for bad or altered times. Under prudent management and the exercise of foresight, the business should remain on a sound and profitable footing, and continue to be a great success.

Mr. Edward Manville, M.I.E.E., in seconding the passing of the accounts, drew attention to one or two points which he thought of some importance. He referred to the fact that the board of the company had always set their faces against, in their opinion, wasting time and money on the building of racing cars. It had been held amongst a number interested in the trade, both abroad and at home, that in order to make a successful touring car you must first of all build successful racing cars. They had produced what had proved to be an exceedingly successful type of touring car, without ever constructing or attempting to construct a racing car, so that they had, he thought, at all events succeeded in proving that it was not an essential point towards success in the manufacture of touring cars. Mr. Manville, continuing, made the very gratifying announcement that just before the meeting of the shareholders important contracts for the export of a number of the company's cars into other countries had been entered upon. One, at all events, of those places was where some of the best motor cars in the world were supposed to be produced. Given skilled and intelligent management, as exemplified amongst their officials, the financial results of building cars were at least equal and perhaps superior to those attained abroad. He particularly wished to draw attention to the fact that the company was an English one, in the true sense of the word, viz., that not only was the capital entirely in English hands, but the cars were made by English workmen in England, thereby giving employment to the British mechanic, and assisting to establish an industry in this country. Mr. Manville concluded his remarks by a very high tribute on behalf of himself

and the other directors to the extraordinary application which the chairman of the company had always shown towards the interests of the shareholders.

The chairman subsequently, after replying to a few questions, drew attention to the enormous obligation which the shareholders were under to those concerned in the actual working of the company's affairs. He specially referred to Mr. Martin, the engineer; Mr. E. M. C. Instone, who carried the burden of the commercial work on his shoulders; the secretary and his staff, and to Mr. Stratton, the London Manager of the Company, to all of whom were due the heartiest thanks of the directors and the shareholders. He said he thought that no board could have a staff who had so entirely at heart the interests of the company, and who were so keen in their work, and so desirous of laying good results before the shareholders. In this category must also be included the foreman of the works. This resolution of appreciation was seconded by Captain C. C. Longridge, and carried with acclamation.

Mr. Percy Griffiths, M.P., in proposing an extra remuneration to the directors of 2½ per cent. on the net profits, under the provisions in the articles, said the board as a whole had rescued the company from a state of practical bankruptcy, and had brought it to its present prosperous condition, and made a national asset of the concern.

This proposition was carried unanimously, and the chairman then proposed the confirmation of the election of Mr. A. H. E. Wood and Mr. G. S. Barwick as directors of the company, who had during the past year been added to the board by the directors.

A. Darracq and Co., Limited.—The report of this company shows a net profit of £152,664, out of which the directors recommend a dividend making 20 per cent. for the year, to transfer £100,000 to reserve, and carry forward £27,174. Large additions have since the date of the last report been made to the company's works and plant at Suresnes, France, which has led to a considerable increase in the company's business. The full benefit of these additions will not, however, be felt until the 1906 season. The

purchase of the big premises in Lambeth, which we announced recently, is also confirmed in the report.

Rover Company.—At the meeting of the shareholders last week, presided over by Sir Frederick Dixon-Hartland, M.P., at Coventry, a dividend of 10 per cent. was declared. The chairman confirmed the great development of the business which had taken place during the past year in the motor department, the manufacture of motor cars having proved satisfactory, and he said that this branch of their business had before it a very bright future.

NEW COMPANIES REGISTERED.

British Buffalo Marine Motor Company (Limited).—Capital, £5000 in £1 shares. First directors, W. A. Cloud, H. J. Nichols, A. M. I. M. E., W. H. De Russett, C. H. De Russett, and E. W. De Russett.

Chiswick Motor Omnibus Company (Limited), 333, High Road, Chiswick.—Capital, £5,000 in £1 shares. First directors: C. T. Sutton, E. de Gruchy, R. Emerson, T. P. Singer, and J. Kent.

Gnome (Limited).—Capital, £100 in £1 shares. Object, to take over the business of the Gnome Motor Car Company, 110, High Street, Manchester Square, W.

Seymours (Limited), 20-22, Brompton Road, London.—Capital, £20,000 in £1 shares (10,000 seven per cent. preference). Object, to establish agencies for buying and selling motor cars, &c. The first four directors are to be appointed by R. S. Harger.

Stevens Tyre Company (Limited), 9, Fenchurch Avenue, E.C.—Capital, £2,500 in £1 shares.

Strand Motor Company (Limited), 231 and 232, Strand, W.C.—Capital, £5,000 in £1 shares. Object, to carry on the business of tutors in motor car driving, engineering, and employment-bureau keepers. First directors, N. A. Medawar and C. E. Handley.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.L.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

24275. 15th November, 1904. Improvements connected with Motors and Driving Gear suitable for Motor Road Vehicles and the like. Frederick W. Lanchester, Armourer Mills, Montgomery Street, Sparkbrook, Birmingham. This invention relates to an improved construction of combined motor and change gear mechanism for power-propelled vehicles. It consists in an arrangement of motor in which eccentrics are employed in lieu of cranks, and in which a transmission shaft passing through the motor shaft to which the driving eccentrics are attached is adapted to be geared to the motor shaft either by a direct clutch or by epicyclic change gear, the transmission shaft being employed for the propulsion of the vehicle. There are five figures. Fig. 1 is a sectional elevation of a three-cylinder motor. The motor is constructed of the ordinary reciprocating type, but in lieu of a crank-shaft it is fitted with a hollow shaft, *a*, furnished with eccentrics, *b*; excessive friction is prevented by the employment of rollers, *c*, held in position by a suitable cage, *e*, between the eccentric and eccentric strap in the manner of a roller bearing. Passing through the hollow shaft, *a*, is a transmission shaft, *f*, which is furnished at one end with a sliding friction clutch, *g*,

reverse motion, as may be required. A series of three gears, as indicated by *j*, may be conveniently employed, consisting of reverse, low gear and compound gear, as employed on Lanchester cars.—October 25th, 1905.

2207. 4th February, 1905. An Improvement in Self-Propelled Road Vehicles, Heavy Motor Cars and the like. James H. Mann and Mann's Patent Steam Cart and Wagon Company, Limited, Pepper Road Works, Hunslet, Leeds. This invention consists in dispensing with the usual long rear or main axle having a road wheel at each end, and providing instead two short axles, one on each side of the vehicle, quite independent of each other, and driven by separate trains of gearing from an intermediate, or the crank or the driving shaft of the motor. Each axle has two bearings, and carries a single wide road-wheel or two narrow ones between the bearings. These short axles may revolve in the bearings, or be fixed in the same and the road wheels driven. There are four figures. Fig. 2 is a plan with the body removed; *aa'* indicates the inner frames or frame

tions for carrying respectively the ends of the short fixed axles, *ff', f'f'*. The wide road wheels, *g, g'*, are mounted loose on the separate independent fixed axles, *ff* and *f'f'*, respectively, and have secured to them the gear wheels, *h, h'*, gearing with the pinions, *i, i'*, driven by differential gearing from the motor of the vehicle. Radius rods are used to keep the gearing properly in mesh, and other radius rods are fitted to tie the springs, *e, e'*, to the inner frames to take any side strain. This invention has the advantage of obtaining great flexibility in the connection between the body or frame of the vehicle and the main driving road-wheels, and enables the road-wheels to adjust themselves better to the ordinary roadway.—October 25th, 1905.

PASSING EVENTS.

To Save the Motor 'Bus from the Promoter.

ALMOST too much praise of the motor 'bus is now appearing in the daily papers. Everybody has begun to recognise its value, and the numbers of the people who travel by it are legion. It has firmly established itself in popular favour, and if the number of motor 'buses plying on the usual routes were to be doubled or quadrupled we think we should be quite safe in asserting that they would all be full of passengers. The type of praise, therefore, of which the motor 'bus is now being made the recipient—we might, perhaps, say the victim—is quite unnecessary from the ordinary business point of view. It can have but one explanation, that motor 'bus company promotions on a large scale are in contemplation, and have passed through the earliest stage—the stage in which the "puff preliminary" is diffused throughout the Press.

Well, we are getting nervous about all this. We have always been the champions of the motor 'bus, and we hope to see the day when the poor slaves of the horse-drawn omnibus will find other fields of activity more suited to their anatomy, and that then every 'bus in the Metropolis will be motor propelled. But we have seen indiscriminate, illicit, and unprincipled company pro-

motion make such havoc in the past with the whole motor car industry that we dread seeing it applied even to *one* thriving department of it. From the very first THE AUTOMOTOR JOURNAL has been opposed to the ill-considered promotions, which have done more than anything else to prejudice the automobile movement in the eyes of the public, and to interfere with the approach of its true prosperity. At the commencement of the movement the unprincipled operations of company promoters, who cared nothing for the industry, but merely desired to reap profit from their financial operations, did more to injure the automobile movement than even restrictive legislation or the ingrained conservatism of the British people. We alone opposed and exposed in the plainest possible language these unprincipled operations, at the time when the automobile industry first fell a victim to them, and the articles which we then wrote have frequently been quoted and referred to by the leaders of the movement in articles and speeches on the question. More recently, when there were rumours of a whole string of projects being in readiness to bleed the British investor by exploiting the public interest in the motor 'bus for the purpose of floating and financing wind-bag companies, we again adopted a hostile attitude to such promotions, and pointed out their dangers, with the result that for the moment they were put back to their pigeon holes to await a more "convenient season." Attempts are, we have reason to believe, being once again made in the same direction. Should these attempts succeed on at all a large scale, they will be certain to cripple the motor 'bus industry for a long period of time. Those companies which have already shown themselves capable of dealing with the situation are entitled to confidence. Should they desire further capital, the situation might be worthy of consideration, but we strongly advise the public against having anything to do with bubble 'bus promotions by new companies on a pretentious scale and questionable financial basis. If they do, they will not only lose their money, but interfere with developments which every Londoner has at heart—the substitution of the motor 'bus for the horse-drawn variety.

One Effect of the Olympia Exhibition.

WE have already indicated some of the general tendencies of this year's great automobile Exhibition, and we shall continue to deal with them in the present and subsequent issues. But there is one effect which this year's Show is producing (due probably to the larger number and increased importance of the exhibits), to a greater degree than has ever occurred before. We refer to the attention which it is attracting on the part of the general Press. Articles have been appearing about it in every type of newspaper. Many, indeed most of them, besides mainly referring to the chief features of the Exhibition, are doing what they have never done before, *i.e.*, recognising the extent to which this present Exhibition proves, not merely the great development of the British industry, not merely the general progress which has been made in motor car construction, but are recognising that there is now no question that road transport will, in the near future, be universally transferred from the shoulders of the horse to the cylinders of the automobile engine. Automobilists, of course, have been firmly convinced of this long enough ago, but now that the general Press and the general public are coming to recognise and adopt this attitude, the effects are sure to be almost incalculable. They are certain to profoundly affect legisla-

tion. As long as the future of the automobile movement was in doubt, as long as it was looked upon as quite an open question whether the horse would hold its own and perhaps even ultimately triumph over the automobile, reactionary cranks, like Sir Ralph Payne Gallwey and Lord Willoughby de Broke, were sure of a hearing, and no one could quite calculate what mischief they would do. With the change of attitude of the general Press, however, they will be regarded with much less patience. When the English public regard the triumph of a movement as certain they invariably bow down before it. The Press is now coming to regard the triumph of the automobile as certain. What the general Press says to-day, the public will think to-morrow, and the complete emancipation of the movement is nearly certain to be the ultimate result. This effect is a by-product of the Exhibition, but an important one all the same, and shows amongst other things how valuable great Exhibitions are even in ways not originally contemplated.

The Importance of the Car to the Doctor.

AS was mentioned by us, when we dealt with the various sources of evidence which the Joint Committee of the A.C.G.B.I. and the Motor Union collected for the assistance of the Royal Commission on the Motor Acts, very valuable information was supplied by members of the medical profession who have found the automobile such an assistance and such a boon in their practice. In spite of the public-spirited action of these doctors in assisting the Joint Committee, we are pleased to see that the matter is being taken up independently by the profession, and that the current number of the *Lancet* is publishing an account of the formation of a committee of medical motor car users, containing a long array of names of important members of the profession who wish to put their views before the Commission, and that the Royal Commission have signified their willingness to hear two witnesses—Mr. Lockwood and Dr. Bruce Porter—on behalf of the Medical Committee on the 29th instant. A large number of doctors who use cars, however, are anxious to have their views placed before the Commission, and the committee will be in a position to bring such views to the cognisance of the Royal Commission, probably by means of the two witnesses whom the Commission has elected to hear. Those having any points to bring forward should address them in writing to Dr. Bruce Porter, 6, Grosvenor Street, London, W.

That medical men, who have been very progressive in adopting the automobile for professional purposes, have decided on taking this independent action, is an extremely eloquent testimony to the value which they have found the motor car to possess for them. Its value is great, of course, in towns, but it is greater still in the country. In fact there is no doubt that the expense of upkeep of a light automobile is so much less than that of a horse and trap, one of which at least are essential for every country practitioner, as to neutralise the somewhat greater initial cost in an exceedingly short period of time. But that is a relatively small matter. The horse is a very tirable animal, and his effective radius is diminished by muddy roads and bad weather by about 50 per cent. Not so the car, while above all in cases of emergency the higher speed of the automobile has a value which many poor sufferers, and above all their anxious friends and relatives, have fully learned to appreciate. Kipling was not exaggerating in the least when he described the throb of the doctor's car as sounding to the ears of the anxious and waiting mother "like the beat of an angel's wing."

D

The Right Spirit.

EVERYONE who takes an interest in the automobile movement will be pleased to learn that Lord Montagu of Beaulieu intends to continue editing and managing the *Car* and the other publications connected with it, which he started some years ago, and has brought to their present degree of popularity. A good many people surmised that Lord Montagu, though probably nothing short of a surgical operation would eradicate his enthusiasm for, and devotion to, automobilism as a pastime, would retire from active journalism on taking his seat in the House of Lords. This, however, is not Lord Montagu's disposition at all. As we pointed out some time ago, he is a hard and persistent worker, and his determination to keep his seat in the editorial saddle is what all who knew him well, anticipated. He makes reference to the subject in the last number of the *Car*, and in just the right sort of tone and spirit. "There is no need," he says, in effect, "at the present day that Peers should not do honest work. The idle drone notion is a thing of the past. In fact, most members of the Upper House are very hard-working people." It is, however, the means of benefiting automobilism which the editing and managing of an automobile journal gives him, that is evidently its chief attraction in Lord Montagu's eyes. It is pleasing, too, to find that he takes the proper and the highest view of journalism, whether general journalism, or journalism confined to some particular subject. "Surely no nobler ideal can be found," he observes, "than the endeavour to guide the minds of one's fellow-men in the channels which one honestly believes the right channels, and fighting for a cause or causes in which one believes."

A Testimonial to Automobile Journalism.

LOOKED at from another point of view, Lord Montagu's decision is a testimonial to the value and importance of automobile journalism at the present day which it would be hard to over-rate. That an active and strenuous, capable and hard-working man with a firm foot on the ladder of political advancement, and a seat in the House of Lords, recognises the opportunities for good which automobile journalism affords, that the chances for benefiting the movement which it provides are so valuable, and that the automobile movement itself is of such supreme importance that he is determined to continue to devote the greater part of his time to journals devoted to its advancement, is a striking commentary on the position which automobile journalism has attained. When the automobile movement first began in this country and when the first automobile journals came into being, if anyone had said that in less than ten years time a man of Lord Montagu's position would have used language of the kind we have quoted above in reference to automobile journalism as a field of usefulness and an important journalistic department, he would have been smiled good-humouredly out of Court. But the whirligig of time has brought its revenges. Automobilism touches human life and general progress at so many points that there is, after all, no other branch of journalism—journalism that is devoted to any *special* subject—which has so many opportunities (in addition to fighting its own particular battle) of promoting enlightenment generally and benefiting the cause of universal progress in such a variety of ways.

A New Hero of our Streets.

WE are glad to find that the enterprising journalist has at last discovered the man who drives the motor 'bus, and recognises that self-propelled locomotion in this form is producing a very creditable and really quite a high type of humanity. A representative of a sprightly morning daily contemporary, by the exercise of that magic of which the enterprising journalist is a master, was favoured with permission to sit on the seat beside the driver of a Vanguard 'bus (a privilege which is accorded to few), while that vehicle made its way from the savoury purlieus of the Elephant and Castle to the comparative rusticity of Cricklewood. He was enthusiastic about the capabilities of the driver, and has provided him with a most picturesque testimonial.

Shaving past within seven or eight inches of the off wheels of dilatory horsed omnibuses, flashing along a row of stationary electric tramway cars, spinning round carts, drays, and the like, the "Vanguard" man never for a moment hesitated or made a mistake. And that, too, despite a thick fog which gave everything a shadowy indefinite appearance. All other classes of vehicle were passed, except private motor cars. The horsed omnibuses looked foolish as they blundered stolidly along. But there was no suggestion of risk in this speedy, agreeable method of locomotion. Keen, intelligent watchfulness was depicted on the "Vanguard" man's face as it peered steadfastly through the fog. Not for a moment during the nine-mile journey did he turn his head.

It is a true picture, and we are glad it has been given currency in a popular morning paper, for really, after all, few people recognise the high capacity, the unerring judgment, the Spartan control of temper, and not unfrequently the real courage which the motor 'bus driver of to-day has to call into exercise, not merely once or twice in the day, but a dozen times on every journey—a journey alone rendered possible by the extraordinary degree of perfection to which the manoeuvrability of such vehicles has been brought. We have all been accustomed from childhood up to look upon the locomotive driver, to whose judgment and care the lives of a large number of passengers are entrusted, as a good deal more than "half a hero"; but when all is said and done, his performances are nothing to those of a motor 'bus driver. The engine driver has not to *steer* his trainload of confiding passengers at all. He has simply to look out for signals. But the motor 'bus driver often, with his cargo of humanity, has to dodge in and out of traffic, and be not only his own engine driver but his own signal service as well. It is a strain, no doubt, but from all we can see it is developing a fine type of man, and one who will not take a back place when, if ever, the various types of manliness that different conditions of society have developed are adequately compared with one another.

ONE of those nervous old gentlemen who seem to think that more police persecution is a cure for everything, has been writing to the papers complaining how greatly he has been frightened by motor cars during the recent thick fogs. On one occasion he says "the traffic was disorganised and crossing the road dangerous . . . I saw several going *quite fast* and one nearly ran into me . . . Could not the police act in this matter?" Comment on this sort of thing is really needless, for doubtless an elderly gentleman of this kind, if one motor car had warned him of its approach by the use of its hooter, would have promptly jumped under the wheels of another.

THE OLYMPIA EXHIBITION.

ALL those who take any interest in these great automobile shows already know, either by personal experience or from the vast amount of matter that has been written on the subject, that the Fourth International Motor Exhibition, organised by the Society of Motor Manufacturers and Traders, is now in full swing at Olympia, and that it is fairly eclipsing everything of the kind that has been held hitherto. As an example of good organisation, it is all that could be desired, and, as a spectacle pure and simple, it is extremely impressive. The vast building is quite as crowded, if not more so, with exhibits and spectators, than it was last February, in spite of the great improvements and extensions made to the annexe. It has during the week, up to the time of writing, been thronged daily with an enthusiastic gathering, the great majority evidently intent upon seeing as much as possible in the comparatively short time available, and bent upon securing delivery by booking the particular cars that take their fancy well in advance.

Most of the manufacturers of pleasure vehicles are to be found in the lofty main hall, with the heavy commercial vehicles arranged at the far end, while the motor-boats, skirted around by the stalls of carriage-builders, and of those firms whose cars have been crowded out of the larger building, form a most attractive display in the less lofty annexe; in the gallery are the great tyre companies, and, close to them, the

numerous well-known firms supplying accessories of all and every kind. Very brilliant and gay has every part been made to look, and many are the artistic or ingenious devices by which the attention of the visitor is attracted to this or to that stall. Most of the stands and signs have evidently cost their owners a considerable amount of thought, as well as money, and the net result is unquestionably a huge success.

To mention but a few of the specially striking erections in the main building, the stalls of the Argyll Company and of the New Arrol-Johnston Company, as also the hanging signs of the White Steam Car firm and the Du Cros Mercedes Company are particularly prominent, as is moreover the large brass "Napier" nameplate above the stall of S. F. Edge and Co. Supported upon pillars, the Argyll Company have a large model representing the frontage of their enormous new works at

Alexandria, while equally applicable to its owners, and therefore suggestive to motorists, is the extremely artistic stall of the Arrol-Johnston Company (designed by Mr. Alec W. Kirk), with its raised central shrine containing the firm's Tourist Trophy winning car.

On entering the annexe, the first sight to meet one's eye is Napier Major towering up above all the other exhibits, and forming a very popular "side show" in itself for those who care to walk upon the deck. Several other well-known motor boats are also there, including De Dietrich II. and the two Panhard boats. Panhard II., by the way, floats in water in a large tank, and the other two boats just mentioned are shown by Messrs. Jarrott and Letts, and by Messrs. J. E. Hutton, respectively. Near by, in striking contrast, are one of the powerful marine gas engines built by the Thornycroft Company, and the cleverly arranged, old-fashioned "court house" where

the "judges" are supposed to "decide." Even the much-despised gallery has far more interest than many an entire exhibition of the past has possessed for the buying public, the result being that it receives its full meed of attention from the visitors, and is, in fact, at times almost uncomfortably crowded. The stall-holders have succeeded in making an excellent show, in spite of the somewhat restricted space at the disposal of each, and many of the stands are exceptionally well arranged and beautifully decorated, as, for instance, those on

AT OLYMPIA.—His Majesty the King's new Car—a handsomely appointed Daimler fitted with every improvement which has lately been introduced either in chassis or carriage construction. Naturally enough this is one of the sights of the Show.

which Messrs. Melhuish and Co. display hundreds of useful tools and Messrs. Godin show off their special lamps.

On these occasions there are perhaps fewer exhibits having an historic interest than has hitherto been the case, and except for the Arrol-Johnston Tourist Trophy winner and the Rolls Royce second place holder in that event, Lancia's famous 120-h.p. Fiat racer was about the only example. The new car built by the Daimler Company for H.M. the King, should, however, also be included in this category of famous vehicles. It is but natural, in view of the magnificent examples of motor car design and construction—ready for those who are anxious to buy cars for their own use next year—that comparatively little space can be spared nowadays for even the most interesting reminiscences of past triumphs.

To the motoring public, and even to many of those

...ams Hewitt Company, and including, on the one side, such omnibuses as the Wolseley, the Clarkson, Straker-Squire, Simms, Arrol-Maudslay, and Dennis, to say nothing of others, the entire field for self-propelled vehicles well covered. They include, moreover, those new makers, as well as numerous entirely new models now introduced for the first time by firms whose names are already quite familiar.

Continental Competition.

From the Continent, however, there is also a truly representative showing, and the vehicles from France, Germany, Italy, Belgium, and Switzerland are worthy competitors in both the pleasure and commercial branches of the industry. With such powerful and excellent models to head the list of touring cars as the 70-h.p. Mercedes, the 50-h.p. 6-cylinder Panhard, the 50-h.p. De Dietrich—and others that come within the same category—with such universally-appreciated small cars as the 6-h.p. De Dion, with such motor 'buses as are sold by the Milnes-Daimler Company,

Messrs. Straker and MacConnell, Messrs. De Dion Bouton, the Motor Car Emporium and others, it will still require herculean efforts on the part of manufacturers in this country if they are to secure and keep any very great lead on such powerful rivals. Owing to the rapidly increasing demand for public service vehicles, there is an opportunity for even newly-established firms to obtain a sound footing in this branch—owing to the present inadequate supply. Nevertheless, it is certain that the "survival of the fittest" will be the principle upon which the success of any firm will depend.

AT OLYMPIA.—An Argyll Landaulette.—The chassis of this vehicle is the standard 14-16-h.p. model, which is also illustrated on this page.

whose business it is to keep closely in touch with the industry, the Exhibition this year cannot but be bewildering. The ever-increasing number of excellent types, the vast number of improvements that are in evidence, and the wonderful strides that have been made in rendering the pleasure car of to-day the essence of luxury, comfort and smartness must all tend to confuse the most conscientious and painstaking of visitors. The remarkable progress that has been made in all these directions undoubtedly has the result, however, of providing infinite satisfaction to those who visit the Show with a definite object in view, and a full knowledge of what it is that they desire to purchase.

It is this very multiplicity of interests and variety of models that renders it quite impossible for any report of the Show to be at the same time useful and thoroughly comprehensive. Every well-designed car—and in many cases some of its accessory parts alone—requires a considerable amount of space all to itself if even bare justice is to be done to it. Thus it is that we can only hope to give a general idea of some few exhibits in this article, reserving our columns as far as possible for dealing with the majority of those not already treated in our own much more satisfactory manner—in separate articles—now and in succeeding issues. This we hesitate the less to do because of the special tables given by us this week and last week, in which—even if not absolutely complete (through no fault of our own)—the leading characteristics of the pleasure cars and the commercial vehicles are set out, in a most compact form, convenient for ready reference.

British Progress.

Of truly British cars there is a splendid collection at Olympia, and, taking them all in all, no other country can to-day claim superiority. Ranging as they do from that wonderfully perfect piece of mechanism, the 60-h.p. six-cylinder Napier, to the remarkably well designed little car now built

AT OLYMPIA.—View from behind of the popular 14-16-h.p. Argyll Chassis, which is suitable either for a roomy side-entrance or landaulette body. An example of the latter type is illustrated at the top of this page.

AT OLYMPIA.—View of the Crawshay-Williams Chassis, which is now exhibited for the first time. It is a substantially built chassis of the chain-driven type, is fitted with a four-cylinder engine, multiple-disc clutch, and "Mercedes" type of gear, giving three speeds and a "reverse." Ball bearings are employed throughout the transmission, except on the chain sprockets, and the gear-box is carried on a special three-point suspension.

America as a Rival.

Although America has naturally not as yet made her extraordinary powers, of turning out good machinery at a low price, felt with much severity in the English automobile market—except in regard to low-powered low-priced vehicles, and very noticeably with steam cars—yet the few really well-known makers from across the Atlantic give every evidence at the Show of their great vitality. No stall makes a finer display of luxurious carriages than do the builders of the finest parab
it is
that,
and

American Motor Car Company are deservedly second to none for "the man of very moderate means," with their Oldsmobiles and Cadillacs, respectively. Then, too, there are the Winton cars, which strongly appeal to many motorists, and are sure during the coming year to be met on our English roads much more frequently than hitherto, since—like the White steam cars—the latest models conform so much more closely to English requirements. Other cars from the U.S.A. include the "Maxwells."

6-Cylinder Cars and Town Carriages.

se as
con-
ear in

AT OLYMPIA.—The new Adams Hewitt Chassis. Since last year, when the car was first exhibited, the chassis has been entirely re-designed, and it is now an extremely interesting example of a well-made British car based on American lines. It has a large slow-speed horizontal engine, two-speed epicyclic gear, and single chain drive to a live-rear-axle. The axles are connected together by long leaf springs which also form the main side members of the frame. Several very ingenious features have been embodied in the construction, however, which render the car quite an original design.

AT OLYMPIA.—One of the latest 10-12-h.p. Coventry Humber Cars. These popular vehicles have been a centre of attraction since the opening of the Exhibition. View of the engine and gear-box appears below.

way of comparatively light automobiles, *i.e.*, if we leave out of account the enormous amount of work that has been done in connection with motor omnibuses and lurries. At Olympia, cars having 6-cylinder engines are shown by at least ten firms, including those of Panhard, Gladiator, Berliet, and Clement—from France—as well as the Napier, Rolls-Royce, Ariel-Simplex, Belsize, Standard, and Orleans models.

Then, in the way of petrol cars designed to appeal to that class of user with whom electric carriages have hitherto been alone in favour, there are quite a number to be seen. The Electromobile Company themselves, who exhibit their latest electrics, were amongst the first to realise the demand for such cars, and it was for them, we believe, that the Napier landaulette (to which we refer more fully elsewhere) was originally produced. Much, of course, has been done by many of the best-known makers to render their standard types of chassis suitable for such work, but we refer chiefly now to the special cars in which the engine is hidden away beneath the floor or beneath the

seat, and not to those that retain the touring car type of bonnet. In the design of such "mock-electrics," firms—like the Wolseley Company—habitually employing horizontal engines, naturally had an advantage initially, but some such carriages—like the Napier—have vertical engines. Two of the most strikingly novel cars at the Show—both of all-British manufacture—are the Rolls-Royce, with its neat little 8-cylinder engine, and the N.E.C., with its 4-cylinder horizontal engine, both of which have been described by us within the last fortnight. Motor cabs present very much the same characteristics, in that they also are intended for work in town, and one of the neatest of these is exhibited by Messrs. Straker and MacConnell; it, unlike either the Dixi model or the Vauxhall "hansom"—both

of which are also on view—has a twin-cylinder vertical engine underneath the front seat.

Beautiful Carriage Bodies.

So artistic in design, luxuriously upholstered and beautifully finished, are many of the carriage bodies which are to be seen on the various stands, that it is almost invidious to mention only one or two in particular. If, however, any of our readers are visiting the Show before it closes, this Saturday, they may be advised to take a look at some of those on the Daimler, the White and the Dennis stalls, as also at the Duke of Westminster's car on Messrs. Lawton and Co's. stand. Considerable ingenuity has also been brought to bear on improvements in design from a utilitarian point of view, Messrs. Mulliner, for instance, having a landaulette with seating capacity inside for three passengers, the third seat being provided for by carrying the covered portion forward alongside the driver's seat; another case in point is the convertible body made by Messrs. W. and F. Thorn, but several other large carriage-builders have designs that are well worth attention.

The 10-12-h.p. Humber Car.—View of the Engine, showing the Crank-chamber which is divided vertically instead of horizontally, and the very large inspection doors which this form of construction permits. The commutator on the end of its inclined shaft is, it will be noticed, in a very accessible position.

The 10-12-h.p. Humber Car.—Interior view of the Gear-box, which has a single sliding member for giving three speeds and a "reverse." A direct drive is obtained on the top-speed, by means of jaw clutches, in the usual way. Ring-lubricated bearings are, it will be noticed, a feature of this gear-box.

AT OLYMPIA.—Italy's latest production—the Bianchi Car—which Messrs. Straker and MacConnell are introducing into this country. A fully illustrated article describing the features of this well-made vehicle appeared last week.

1906 Petrol Cars.

Most of the best petrol cars are now so well known to our readers that only very brief reference is called for, particularly as we have in many cases already recorded even the improvements that have been made for next year. As stated lately, but slight alteration has been made by the Daimler Company, except that the price of their famous cars has been much reduced; the Napier exhibit consists chiefly of the 6-cylinder cars of 60-h.p. and 40-h.p.; several new Siddeley models, which cannot but meet with a great demand, are being introduced by the Wolseley Company, in addition to the already popular horizontal-engined cars; all the Mercedes chassis, except the 25-h.p. model, have bearings on the crank-shaft and a direct drive the gear-box, as on the 70-h.p. car, described very fully a few weeks ago; the Ariel cars now have a change-speed-gear of the "Mercedes" type, in addition to various minor improvements; the new De Dietrich models are even better than those of last year, and the very simple engine now employed has been altogether redesigned; the new De Dion types include a more powerful 4-cylinder model than the 15-h.p. of this year;

Cars of Moderate Power.

A very important development is discernable in connection with cars of moderate power—that type of car, in fact, which is, to all intents and purposes, specified by the present Tourist Trophy rules. We refer to the appearance at Olympia of such new models as the 12-15-h.p. De Dietrich, the 14-22-h.p. Germain, the 12-16-h.p. Fiat and the 14-h.p. C.G.V. It is significant, and will, we feel sure, be welcomed by many motorists, for the tendency up to now has been for such first-class Continental firms as these to confine their attention to the construction of much more powerful

vehicles. It is, of course, a type of car that many British makers have adhered to, and there are, at Olympia; quite a large number having engines of a corresponding power. Most of the firms who took part in the Tourist Trophy race have stalls there, and consequently those wishing to purchase this useful kind of vehicle have a large variety from which to make a selection.

Notable amongst such well-known British models are the Thornycroft, the Argyll, the Arrol-Johnston, the Rolls-Royce, the Simms, the Swift, and the Humber, the last-mentioned make having been brought up to a remarkably high state of development during the past year or so. There are, too, cars of about the same power shown by the Maudslay, Dennis, Orleans, Speedwell, Standard, and Rover Companies. The Leader is another instance in point, though this little 4-cylinder car was not one that figured in the Isle of Man last September.

Somewhat more powerful cars, but still low-powered in comparison with their larger models, are also shown by Messrs. J. W. Brooke and Co., and the Burlington Carriage Company (16-20-h.p. Delaunay-Belleville).

Other New Touring Models.

In addition to those already mentioned as such, the entirely new cars shown by English makers include the two Legros and Knowles models, the chain-driven and

AT OLYMPIA.—A private motor cab. One of the most striking vehicles at the Exhibition, which is shown in the Annexe, by Messrs. Straker and MacConnell. Curved sliding doors are fitted to the body which is luxuriously upholstered and fitted with every convenience. Under the driver's seat is the twin-cylinder 14-h.p. engine; a Mercedes type of gear-box is fitted which provides three forward speeds and a "reverse," and the rear wheels are driven by side chains.

Light Cars.

Strictly speaking, the Adams-Hewitt should have been included in the preceding paragraph, for it has been improved out of all recognition during the past season, even though it still retains the leading characteristics of the American "run-about"; it is, however, essentially an instance in which no adequate idea can be conveyed in a few brief sentences, and is a car of which we hope to give a full description in an early issue.

Most of the other light cars—and there are many at Olympia—are already more or less familiar to every motorist, and, although each and all have been brought up to date in one way or another, they practically remain unaltered in all essentials. The 6-h.p. models of the Wolseley Company and of Messrs. De Dion Bouton continue to hold their premier place

al ex-

The 24-h.p. Albion Car.—Side view of the new chassis, showing pressed-steel frame and enclosed side-chains. In front of the engine is the Albion mechanical lubricator, A, which we have already described in detail. Some radical departures from orthodox practice have been introduced into this new model.

two chain-driven types of touring car having four-cylinder engines, Hele-Shaw clutches, and a "Mercedes" type of change-speed-mechanism; prior to the opening of the Show, it was impossible to include any full description of these vehicles, but we hope to do so shortly. Amongst other new cars shown for the first time are those exhibited by Messrs. Bell Brothers and the Vulcan Motor Manufacturing Company.

Of Continental construction, mention should also be made of the 1906 Minerva cars, made in two sizes now having live axles, and of the 20-h.p. Pilain exhibited by Mr. W. H. M. Burgess; the latter has an unusual type of transmission mechanism, which gives a direct-through-drive on the two highest speeds. From America, the chief radical novelties are the two-cylinder and four-cylinder Oldsmobiles, with their vertical engines.

AT OLYMPIA.—The De Dion Char-a-banc with "vis-a-vis" seats. This body is mounted on the same chassis as that used for double-decked omnibuses; it has a four-cylinder 24-h.p. engine, fitted with magneto ignition, a sliding spur-wheel type of gear-box, and the road wheels are mounted on a stationary axle and driven through spur gearing by transverse cardan shafts.

AT OLYMPIA.—An example of elaborate suspension on a new C.G.V. chassis, showing the "C" springs and transverse spring which support the frame at the rear. Specially constructed for Continental use, this model has the steering-wheel on the left and the control-levers in the centre.

cellence of design, and, of course, the Cadillacs and the Oldsmobile "run-abouts" have secured a most enviable reputation for those requiring really serviceable vehicles at a remarkably low figure.

Steam Cars.

Even apart from the White steam cars, the excellent features of which become more and more fully appreciated by motorists each year, the prospects of steam in competition with internal combustion engines for touring vehicles, have a somewhat brighter appearance at the present Show. There is not only the Miesse model, which has undergone but little change since it was last referred to by us, but the Speedwell Company are exhibiting an entirely new Serpollet chassis, on which many radical alterations have been introduced. The engine is, for instance, fixed beneath the bonnet in front, and is now coupled up by a long propeller-shaft with a rear axle of the "live" type. A small steam donkey-pump, quite independent of the engine, operates the fuel and water feed-pumps, so that the system as a whole may be said to constitute a complete departure from that of the earlier Serpollet cars.

The War Office ambulance car, which has been built experimentally for the Royal Army Medical Corps by Messrs. Straker and Squire, and which is on the firm's stand, looks a businesslike machine for the purpose for which it is intended. The internal arrangements are of a very practical nature, there being room on one side for two patients at full length, one

ng arranged over the other. The top one is so hat the whole berth can be brought down ally to the floor level and the patient then n the bed, the berth and patient then being raised back into place, thus making room for a second patient underneath. On the other side seated patients are provided for, to the number of about eight, in addition to the nurse, whilst, underneath, room is provided for spare stretchers. This vehicle, which is shod with Sirdar tyres, is to be tried in connection with the new Army scheme for Central Hospitals which provides for bringing up patients from various outlying military depôts to one central establishment.

Tyres.

One of the most important sections of the whole exhibition, and by no means the least interesting either—even to the casual spectator—is that uninterrupted line of stalls in the gallery where the great tyre companies display the products of their craft.

So specialised and technical is the process of tyre manufacture, and so little is it possible for evidence of improvement to be visible on the mere observation of the finished articles, that a very great deal has to be taken on trust by the purchasing public. There is one great safeguard, however, in the established reputation of the best-known firms, and the motorist is indeed well looked after by them in their constant endeavour to improve, year by year, the wearing qualities of their goods. Dunlop tyres have, as usual, a prominence at the Show which is worthy of their famous name, and a most valuable stock of tyres, including their full range of sizes, is on view. Always endeavouring to effect any improvement in the "accessories" of a tyre, they have this year introduced a new security bolt, which is claimed to be immune from any tendency to "cockle" under adverse usage or conditions. It is a business-like improvement, and consists of lining the canvas tabs with a foundation of

Wheels—

W = Wood; S = Steel.

Tyres—

S = Steel; R = Solid Rubber; P = Pneumatic; l = twin tyres.

rubber, which stiffens them sufficiently to make them very durable and yet not so much so that they do not easily adapt themselves, as before, to their positions when in place. On the Continent few tyres rival the famous Michelin pneumatic, which is manufactured at Clermont Ferrand; and since it has been introduced into England its popularity has been assured by the large number of motorists who immediately availed themselves of the opportunity to use this make. At Olympia these tyres were greatly in evidence, as were those of the well-known Continental Company, whose repeated successes in races—including the memorable first Tourist Trophy—has won for them a fame as widespread as it is well deserved. One of the best known of our English tyres is the Collier, which is peculiar for its construction and its method of fastening, both rendering it extremely suitable for that class of work for which, especially, it has made such a good name. An interesting feature of the Collier Company's stand is the set of tyres taken from one of the Daimler cars used by His Majesty the King. Another tyre which is very interesting in its construction is the Palmer, but its peculiarities are, of course, already well known to our readers. One of the most comprehensive exhibits is that of the North British Rubber Company, who not only show the Clincher pneumatic tyres, but also solid tyres, and the Ducas hollow tyre, which latter we have described in the past. Another firm showing both solids and pneumatics is Messrs. Moseley, who have two lady operators demonstrating the facility of mounting and removing their pneumatics. As usual, the Sirdar Rubber Company make an imposing display of their deservedly famous "Buffer" tyres, which are now being so largely used on public service vehicles throughout the Kingdom. There are few more important items to motor bus companies than the question of tyres, and there are few rubber firms who have laid themselves out more thoroughly to meet the ever-increasing demand on their supply than the Sirdar Rubber Company, who had, of course, established long before a reputation for their goods on pleasure vehicles. Another famous firm of solid rubber tyre manufacturers is the Shrewsbury and Challiner Tyre Company, who exhibit their well-known "World," "Giant," and "Bull" tyres for use on omnibuses, vans, and luries. Messrs. Connolly show the celebrated Goodrich tyres, which are as well-known in America as in this country, and our readers are already familiar with the very strong fastening which forms the peculiar feature of these tyres. Although not actually exhibiting tyres, no reference to this section would be complete without mention of the vulcanisers shown by Harvey Frost and Co. Tyre repair is of such vital importance to motorists that these devices make a direct appeal to all who are interested in economising their tyre upkeep. Readers of our article on modern tyre repair will be conversant with the process of using small vulcanisers, particularly the portable plant which is a speciality of this firm. Non-skids there are in plenty, but those of well-known makes, such as the Samson (Capt. Masui) and the Parsons, are so well-known that they need no comment. It is the same as with the tyres themselves, their popularity is the surest indication of their quality.

AMONGST the earliest visitors to the Olympia Show last week were H.R.H. the Princess Louise, Duchess of Argyll, the Duke of Argyll, K.G., the Dowager Duchess of Sutherland, and Lord Suffield.

The Argyll Motors, Limited's stand at Olympia is a novelty in design, a large model of the new works frontage at Alexandria being faithfully reproduced. This model of the works, which is seen in our photograph of the stand, is 22 feet in length, giving a scale of about half an inch to the foot. The effect is distinctly striking.

Olympia.—The Inaugural Luncheon.—No formal opening took place this year in connection with the Olympia Show, the inaugural luncheon being the only outward and visible sign of any ceremony on the first day. This was a crowded function, practically not a seat in the huge dining-room at Olympia being vacant.

Mr. Sidney Straker, the President of the Society of Motor Manufacturers and Traders, occupied the chair, whilst the Hon. Arthur Stanley, Chairman of the A.C.G.B.I and the Motor Union, was the chief speaker.

Mr. Stanley, in proposing the toast of the day—"The Society's Exhibition"—was gratified to think that it was not a very difficult toast to deal with, as the splendid Show spoke for itself. He referred to automobile times of ten years ago as pre-historic and compared them with the magnitude of the industry which has grown up in the interim. He said that not only were British manufacturers holding their own, after having caught up foreign makers, but that they were taking up their position as the first in the motor car industry. He was somewhat diffident, and said he was afraid he would tread on the sensitive corns of the local authorities—in referring to the subject of "roads." Reforms, he thought, must come gradually, and it would not be wise to take away at once powers of local authorities for local roads, but he hoped, as regards main roads, that these would be placed in the hands of a central body and thereby efficient and economical administration secured. This, he believed, could be done without putting a single penny extra tax upon anybody, by utilising the fines which were inflicted upon automobilists, the taxes on motors, &c., and adding them to the present grants for road up-keep. Together these would more than suffice to provide the funds for the maintenance of the main roads. In time there would evolve a series of

grand, broad, and dustless roads, stretching out in every direction throughout the country with London as a centre. Difficult as the problem was, he was convinced that it would be solved ultimately by means of the automobile.

Mr. Sidney Straker, in replying to the toast, was able to give some interesting facts and figures which went far to confirm the strongly-expressed views of the Hon. Arthur Stanley upon the enormous advances which were being made in the home industry.

The Austin Car.—The important announcement is made by Mr. H. Austin that Mr. Harvey Du Cros, Jun., has been appointed the sole selling agent for this car, all business relating to which will be conducted from 127-130, Long Acre, London, W.C. Models will comprise a 15-20-h.p. 4-cylinder car, gear driven, and a 25-30-h.p. 4-cylinder car, chain driven, delivery of which will be given in January. Mr. Austin is and has been at the Ariel Motor Stand, No. 41, Olympia, during Show week, where he has been the recipient of many congratulations from his numerous friends upon the new enterprise upon which he has embarked.

In the advertisement last week of the Austin Motor Company, of Longbridge Works, Northfield, Birmingham, in a few of the copies printed the figure 1 was, unfortunately, "dropped" in the line which gave the powers of the touring cars for 1906 which Mr. Austin will be building under the title of "Austin" cars. This "dropped" figure made the first car read as a 5-20-h.p. live-axle car. Of course, this should have been a 15-20-h.p. live-axle car.

THE special fête to be held in Paris during the Automobile Salon next month, in commemoration of the Tenth Anniversary of the foundation of the A.C. de France, is announced to take place on December 12th.

AT OLYMPIA.—North-Eastern Railway Parcels Express.—A new delivery van supplied by the Motor Car Emporium, Ltd.

SOME LEADING CARS AT OLYMPIA.

(Continued.)

THE NAPIER PETROL LANDAULETTE.

PROBABLY no automobile is so generally admired for its graceful lines—even by those who are otherwise given to see no beauty in the most handsome of orthodox motor cars—as the electric landaulette, with the swan-like curvature of its dash, and it is little wonder that a demand among those who use their cars largely in town should have sprung up for petrol driven vehicles of similar design. To a firm such as Messrs. S. F. Edge this naturally made a direct appeal, and the designing of a chassis to meet these requirements, without sacrificing the characteristic features which have made the Napier touring cars famous, became at once a problem of urgent importance. Popular supposition accredits the vertical engine as an unsuitable type for any other position but under a bonnet, and yet the Napier Company have not only been successful in making room for one of their four-cylinder models beneath the body, but they have maintained its

longitudinal position in the frame at the same time. One other difficulty to be overcome was the interference of the side chains with a perfectly free entrance to the carriage with such a short wheel base, but this has been ingeniously surmounted by arranging them inside the frame. In respect of the engine, the clutch and the gearbox, the chassis is virtually the standard 18-h.p. model and it carries with it, therefore, an already fully-established reputation. It will be remembered that the first model was exhibited by the Electromobile Company—who took over the sale of these cars from the very first—at the last Olympia Show.

The Napier Landaulette. View of the complete car showing the curved dash and the direct entrance to the carriage which is entirely unobstructed by the side chains.

All the peculiarities in the arrangement of this interesting chassis are illustrated by the photographs which we have taken specially for the purpose, and we also reproduce a photograph of the completed vehicle, which shows very clearly the neat appearance of the finished design. Immediately below the driver's seat is the engine, to which access is obtained through hinged

r
i
l

Fig. 2.—The Napier Landaulette. Side view of the Engine showing the inclined Push-rods, A¹, which operate the Inlet Valves, and the Pressure valve, D¹, for the lubricating Oil-tank, D.

The Engine.

In order to obtain the necessary height for the engine without interfering with the bodywork, it has, of course, been necessary to build it on a somewhat lower level than usual, for which reason it is carried by an underframe supported on transverse members, and the longitudinal members of this underframe are continued to meet the side members of the main-frame in order to thus afford additional rigidity to the construction.

Cast in pairs, the cylinders have all their valves on one side, but the inlet valves are placed above the exhaust valves, and they are mechanically operated by inclined push-rods and rock-levers. These push-rods, A¹, are prominent in Fig. 2, and the same view shows the method of carrying the rock-levers on the inlet-valve cages, A, themselves, so that by removing the large central nuts, A², and slacking back those securing the induction-pipe, the cages—which are also cast in pairs—can be bodily removed with their valves for the purpose of grinding in or inspection. Slotted flanges are employed for the induction-pipe connections, which are visible in Fig. 3, so the nuts for these do not have to be entirely removed in order to take away the cages, A. Coiled torsion springs, A³, are used for controlling the return of the rock-levers and push-rods, but these are, of course, quite independent of the valve springs proper, which are contained inside the cages, A.

On the opposite side of the engine is the carburettor, B, which is fed by gravity from a petrol tank on the dash. Automatic governing of the engine is provided by means of a centrifugal governor, which is interconnected with the throttle-valve, and a Napier hydraulic air regulator, B¹, controls the richness of the mixture for variations of speed. A branched induction-pipe passes from the carburettor to the inlet-valve cages, which, it will be noticed, form particularly neat and accessible fittings.

Mounted on a bracket close to the engine is the multiple "commutator," C, for distributing the battery current to each of the four separate induction coils in turn. From these coils neatly arranged high-tension wires, C¹, are led to the ignition plugs below the inlet-valves. Friction-driven by the fly-wheel is a centrifugal circulating pump which passes the cooling water through each jacket in turn. Immediately below the front of the frame is the radiator, which is of the coiled finned-tube type, while behind, above the bent rear axle, is a water tank. All the water-pipe joints on the jackets are, it will be noticed, in accessible positions above the cylinders. Lubricating oil is carried in a tank, D, situated just behind the engine, and is fed from this by exhaust-pressure to the drip-feed lubricator on the dash. Owing to the unusual position of the engine, it has not been possible to use the orthodox fitting for the starting-handle, and it has even been necessary to intro-

Fig. 3.—The Napier Landaulette. View of the Engine from the left, showing the "Commutator," C, and the hydraulic Regulator, B¹, which controls the warm air supply to the Carburettor.

duce sprockets and a chain in order to overcome the difficulty. The starting-handle is, however, in the usual position in front, but in order to engage it with the starting-gear it is necessary to push a small rod similar to that often provided to relieve the compression when starting powerful engines on large cars.

(To be continued.)

Quevedo Redivivus.—Another Quevedo has arisen in Spain, who has, it is alleged, tried on the sea near Bilbao, and steered by wireless telegraphy from the shore, a motor launch. We are always hearing of this departure, but somehow these wirelessly steered boats never get any forrarder, and, with horrible persistence, they always perform their evolutions in foreign parts.

THE 1906 WINTON CARS.

ALTHOUGH so successful, both here and in America, with their well-known and popular horizontal engines, the Winton Company introduced, at the last Olympia Show, it will be remembered, a new type of car with vertical engine and propeller shaft drive. This is perhaps the most radical departure which any firm can make, and just at first such a venture may fairly be regarded in the nature of an

This latter model has, of course, already been very fully described by us in the past*, and it remains, in all important respects, the same to-day. One important detail to be remembered, however, is that it is now supplied complete, with interchangeable bodies—one a roomy detachable tonneau, and the other a brougham to seat four—which are readily interchangeable. Except as regards dimensions, the vertical models are alike, so the illustrations and description which we give of the 25 h.p. chassis applies in general to the smaller size also.

In adopting the vertical type of engine, the Winton Company have not sacrificed any of the well-known features which are so closely associated with their name; the pneumatic control of the atmospheric inlet-valves and the "fool-proof" change-speed-gear are again the two most prominent features of the system, while there are many special details of construction—such as the vertical division of the crank-chamber, the compound springs, and the gear-driven fan—which make this car unique, even although belonging to a thoroughly orthodox type. Only two forward speeds are available, but the four-cylinder engine is of ample power, flexible, and is easily controlled, so that in practice it is seldom necessary to use anything but the top-gear. In the vertical types, a propeller-shaft is employed to drive the live-rear-axle.

*See THE AUTOMOTOR JOURNAL, October-November, 1904.

Fig. 1.—The 25-h.p. Winton Car. Front view of the chassis, showing the radiator and the manganese bronze front axle.

experiment. With a firm such as the Winton Company, however, success is too well assured to leave any grave element of doubt, and it comes as no surprise that they are making a great feature of the vertical engine this year. Some slight modifications have not unnaturally taken place in the design, while the sizes of the various models have also been readjusted to more nearly suit the requirements of the majority; thus the smallest model has been modified for the English market, but still has a 16-h.p. vertical engine, the 40-50-h.p. car is no longer to be built, so that the 25-h.p. chassis—also fitted with a vertical engine—is now the most powerful of all. Between these is the old standard 20-h.p. car, with the horizontal engine, which has done such yeoman service in the past, and is, in fact, largely responsible for the Winton Company's fame.

Fig. 2.—The 25-h.p. Winton Car. View of the engine, showing the "pneumatic control" Cylinders, A, over the inlet valves, and the Pump, B, which feeds them with air. Also prominent in the view is the Carburettor, C, the Commutator, E, and the Force Pump, D, for the fuel and oil feeds.

Fig. 3.—The 25-h.p. Winton Car. View of the Engine, showing the very large inspection doors in the crank-chamber, which is constructed with a vertical joint so that the entire side can be bodily removed. A gear-driven fan is placed behind the radiator, and the Disc-Clutch, F, which couples the blades to the spindle can be seen in this view.

The Engine.

ONE of the most noticeable features about the engine is that all fittings are mounted on one side only of the crank-chamber, this being done in order to leave the other side entirely unobstructed. It is from this latter side of the engine—which is illustrated in Fig. 3—that access is obtained to the crank-chamber, and not only are large, and readily removable, inspection-covers provided, but the crank-chamber itself is constructed with a central vertical joint, so that the whole of one side can be bodily removed. Independent caps are also fitted to the crank-shaft bearings, so that this may be done without disturbing the crank-shaft itself.

Another peculiarity, which is prominent in Fig. 2, is that the push-rods for the exhaust-valves are enclosed behind inspection-covers, which are screwed to the cylinder-castings, and as the inlet-valves are of the auto-

Fig. 4.—The 25-h.p. Winton Car. Transverse section through the engine showing, on the right, one half of the crank-chamber, H, removed from its normal position. The crank-shaft is held by independent bearing caps so that this may be done without affecting the alignment.

matic type there is not a single valve-spring or push-rod to be seen anywhere. The cylinders are cast in pairs, and, bolted to the top of the casting above the exhaust-valves, are the inlet-valve-housings, A, which are also cast in pairs. Small cylinders, A¹, are cast above each valve, and these contain the pistons, A², which are fixed to the inlet-valve-stems for the purpose of obtaining a pneumatic control on the amount which they are allowed to open under the suction of the engine. This construction is shown more clearly in the sectional drawing, Fig. 4, where the arrangement of the valve-springs is also indicated. Screw caps, A³, are fitted to the tops of the cylinders, A¹, in order to facilitate inspection. Air is pumped continuously into the space beneath the pistons by a simple single-acting air-pump, B. This pump is mounted in front of the engine and is driven, by a connecting-rod, from a crank-pin provided for the purpose on the end of the cam-shaft. Passing through the pipe, B¹, the air reaches a small

reservoir, B² (Figs. 3 and 5), placed between the cylinder-castings, which equalises its pressure, and from this it is led directly to the cylinders, A¹. Communicating with the chamber, B², is another pipe, B³, which is fitted with a hand and foot-controlled valve communicating with the atmosphere. By operating this valve—which is never allowed to close completely—the driver is able to regulate the air pressure and thus control the "lift" of the valves.

Carried by the induction-pipe, C¹—which passes across between the two inlet-valve-chambers—is the carburettor, C. In this, is an annular float made of varnished cork, which surrounds a central jet. Air enters below the jet and passes upwards, direct to the induction-pipe additional uncarburetted air being admitted by an automatic valve, C², in order to compensate the richness for variations of speed. Petrol is carried in a tank at the rear of the chassis, but before reaching the carburettor, it is forced into a smaller tank, situated on the dash, so that gravity feed is always available for the purposes of starting.

(To be continued.)

Fig. 5.—The 25-h.p. Winton Car. Diagram of the pneumatic control system by which the lift of the atmospheric inlet valves is varied by the driver. Also shown is the system of piping for the fuel and oil feeds which are forced from their tanks by air pressure.

THE NEW 12-15-H.P. DE DIETRICH CAR.

It is no small event when such a famous firm as the De Dietrich Company places upon the market a car which, while it retains all the excellent characteristics of their most recent models, can be sold at such a price that it is at once available to that already large, and still increasing, section of the public who fix a maximum of £500 as the price which they are either unable, or unwilling, to exceed when purchasing the chassis of their

There are no striking departures from orthodox practice in the general design of the chassis, but in almost every detail there is evidence of a strong desire to effect some improvement over accepted methods. Although an ordinary cone-clutch has been employed, for instance, it transmits its power in an original way, and is so constructed that it may be dismantled in a few minutes. Similarly with the gear-box, which is of the Panhard sliding-spur-wheel type, provision has been made so that it can be easily taken down without disturbing other parts of the transmission system. Another refinement is the introduction of a spring into the operating gear for the rear brakes, which facilitates their gradual application. Side-chains are, as is usual in De Dietrich cars, employed for the final transmission to the road-wheels, and about 17 h.p. is available from the nominal 12-h.p. 4-cylinder engine.

The Engine.

Inlet and exhaust-valves are alike arranged on the same side of the engine, which has the cylinders cast in pairs. Inspection-plugs are arranged above them, and in those over the inlet-valves are ignition plugs of a special pattern suitable for use with the high-tension Simms-Bosch magneto. Very great care has been taken to protect the high-tension wires, and they are, for this purpose, enclosed in insulating tubes which conduct them close up to their plugs. Instead of having an ordinary screw terminal, the "Oleo magneto" plugs are provided with very neat couplings which enable the wires to be instantly disconnected, while at the same time protecting them from damp, and preventing them

Fig. 1.—The 12-15-h.p. De Dietrich Car. Front view of the new chassis, showing the artistic design of radiator which, although not very pronounced, is nevertheless a characteristic feature of the latest De Dietrich Cars.

cars. Messrs. Jarrott and Letts, who control the interests of the De Dietrich firm in England, have been at considerable pains to have this new model constructed for the English market, for they realised, from the importunate demands of would-be purchasers, how popular such a car would instantly become. And even without the name De Dietrich, this chassis—which is shown for the first time at Olympia—could hardly fail to achieve the success which its merit deserves.

Constructed on the most up-to-date lines, it is, in fact, similar in appearance to the new 40-h.p. and other 1906 models. There is a keynote of simplicity about this "little" De Dietrich chassis, which does much to emphasise its refinement of detail and the strength of its main members; while the external appearance is at once neat and characteristic, its principal distinguishing feature being the artistic outline of the radiator, which bears the blue enamelled emblem of the De Dietrich Company.

Fig. 2.—The 12-15-h.p. De Dietrich Car. View of the Engine showing the Carburettor, the Pressure Valve for the petrol, and the neat fittings by which the high-tension wires are connected to the ignition plugs.

Fig. 3.—The 12-15-h.p. De Dietrich Car. View of the Engine, showing the Simms-Bosch High-Tension Magneto and the belt-driven fan, which has a spring adjustment. On the top of the vertical tube which carries the fan will be noticed a cap, which is provided to facilitate filling the crank-chamber with oil; being fitted with a gauze cover, it also serves as a vent.

from coming loose. The magneto itself is on the opposite side of the engine, where it is mounted on a bracket at the side of the crank-chamber, and is gear driven from the front end of the crank-shaft. No "timing" is provided, either automatically or by hand, but, when starting, the act of inserting the handle causes the ignition to be temporarily retarded while the starting handle is actually in use.

On the same side of the engine as the valves is the carburettor, which has a simple horizontal type of throttle valve provided with an auxiliary-air port which uncovers as the throttle is opened. Mounted on the dash is a small lever interconnected with a needle valve above the jet, and the driver is by this means enabled to cut off the supply of fuel entirely. Pressure feed is employed, and the petrol tank is situated at the rear of the chassis, a small hand-pump being provided for raising the pressure in the tank when starting. No governor is fitted, but the throttle valve is controlled by a hand-lever above the steering-wheel, and it is also interconnected with an accelerator pedal.

Forming the front of the bonnet is the radiator, which is of the finned tube type, and immediately behind it is the belt-driven fan. An exceedingly neat arrangement has been adopted in connection with this portion of the machinery, for the fan is mounted on a vertical tube, which forms a vent for the crank-chamber and an oil filler cup at the same time. Instead of mounting the fan-pulley on the crank-shaft, it is placed on the spindle of the gear-wheel which drives the magneto, and it will also be noticed that a helical spring is provided for automatically taking up any slackness which may occur in the belt. A centrifugal circulating-pump is employed to force the water through the cylinder-jackets and radiator, and this is driven by a chain from the crank-shaft. Drain-cocks are fitted in the jackets to enable them to be emptied when required.

in every way be worthy of the name it bears. Hitherto all Germain cars have been of the chain-driven type, but this new model, which will now be the least powerful of the

reduced, which permits the steering to have a wider range.

(To be continued.)

THE 1906 CLEMENT CARS.

The 18-h.p. Clement Car.—View of the Chassis from above, showing the special suspension for the frame, the live-axle drive, and enclosed multiple-disc-clutch, which are features of these cars. All the 1906 models now have pressed-steel frames and "Mercedes" type gear-boxes.

ON the new Clement cars the alterations have been what may reasonably be termed radical, although at first sight it might not appear to the uninitiated that such is the case. Merely by casually glancing at our illustration, no evidence is at once apparent of any great changes having taken place since we published a similar view of a Clement chassis at the time of the last Olympia Show. This is due, mainly, to the fact that the modifications have been in construction rather than in design, for the

series, has a live-rear-axle driven by a propeller-shaft. In most other respects, however, it retains those constructional peculiarities—of which the separate steel cylinders with their brass water-jackets is the most important—which have for some time characterised Germain vehicles in the past, although a radical departure from the Germain standard has been made in the external appearance by the adoption of a particularly distinctive, but at the same time very attractive, design of radiator.

Constructed of pressed steel, the side-members of the main frame are bent upwards at the rear in order to reduce the angularity of the propeller-shaft and to allow plenty of room for the springs without unduly raising the body from the ground. For the same reason, too, these springs are placed outside instead of beneath the frame, but this is now quite a usual feature in the construction of many up-to-date cars. Shackles being used at both ends of the rear springs, radius-rods are employed to tie the axle-casing to the frame. In front, the width between the side-members is much

Clement cars, which Mr. E. H. Lancaster has made so popular in this country, are still built on the same general system as before.

By far the most important of the new features are the pressed-steel frame and the Mercedes gear-box, but the former is still supported on modified three-quarter elliptic springs behind, while the latter is bolted to an under-frame as it was in the old type. This under-frame, however, no longer supports the engine also, as

it did previously. Another important modification of detail is the introduction of internal expanding brakes on the rear wheels, band brakes having been employed previously.

No alteration has taken place in the engine except that it is now fitted with synchronised high-tension magneto ignition (Gianoli) and has forced lubrication to the bearings. This year the control is obtained by the manipulation of levers mounted above the wheel on a stationary quadrant, instead of by rotating-handles which previously formed part of the steering-wheel itself.

Other slight modifications are the placing of the tie-rod, for the steering-gear, behind the front axle, and the introduction of "push" pedals in the place of

those formerly used, which had to be pressed downwards.

Five different models are being built for the new season, including vehicles of 10, 14, 18, 24, and 30-h.p. Of these, the most powerful has a six-cylinder engine, while the smallest has a twin-cylinder engine, all the others having engines with four cylinders. With the exception of two models, all the chassis are of the live-axle type; but the 24 and 30-h.p. cars are chain driven, and the feature in their transmission is that the differential countershaft casing is separate from the gear-box and is removed from it, so that a short propeller shaft has to be interposed between them. From the engine to the gear-box, however, all models are built on the same standard lines.

A SAFETY STARTING-HANDLE.

Fig. 1.—The Reid-Riekie Starting-Handle.—View of the device fitted to a Car, showing the pawls which hold the ratchet and prevent a back fire from being transmitted to the handle.

ONLY those who have experienced really painful results from back-firing when starting a petrol engine, are fully capable of appreciating the advantage of a safety device for preventing accidents from occurring in this way. In principle, the action of the Reid-Riekie starting-handle—of which we give two illustrations—is extremely simple, for it merely consists in the introduction of a slipping-clutch between the handle proper and the spindle which engages with the crank-shaft; provision for preventing any shock reaching the hand being made by means of a suitably arranged pawl-and-ratchet gear.

In Fig. 2, the device is shown separately, and its action is almost self-explanatory from the system of lettering adopted. On one side of the clutch, A³ B³, the handle, A, forms the principal member, while the other side of the clutch is connected to the coupling, B, which engages with the crank-shaft. When the cap, A⁴, is in place on the thread, A², it keeps the two members of the jaw-clutch engaged on account of the action of the spring, B⁴. As the jaws on the clutch are

Fig. 2.—The Reid-Riekie Starting-Handle.—Separate view of the device showing the flat-bevelled Jaws, A³ B³, which, being only held in engagement by means of a Spring, B⁴, allow slipping to take place in the event of a back-fire, but yet afford sufficient grip to start the engine.

not only very flat, but also slightly bevelled, any pressure in excess of that necessary to overcome the compression of the engine causes them to slip over one another. In order to prevent the least shock being transmitted to the handle, a ratchet-wheel, A¹, is fitted, and this is constantly ready to be engaged by suitably-arranged pawls as seen in Fig. 1. Directly a back-fire occurs, therefore, the pawls prevent the handle from flying back, but the slipping-clutch allows the engine to make its partial rotation in the opposite direction without causing damage.

THE NEW ARROL-JOHNSTON PETROL CAR.—PART II.

(Continued from page 1411.)

The Special Features.

LEAVING out of consideration, for the moment, the twin-cylinder engine itself—since no merely brief description can adequately give a good idea of its con-

formed in one piece with the cylinder-heads and valve-chambers. The exhaust-box employed is very effective as a silencer, but it does not introduce any back-pressure and so absorb power; when used with the smaller engine, at any rate, it even appears to increase the engine power, for we have ourselves seen this engine, under load on the test bench, speed up considerably each time the silencer was connected to it, and slacken down again when allowed to exhaust direct to atmosphere.

Throughout the whole of the transmission gear, roller-bearings of the firm's own make are employed, while ball-bearings are introduced wherever end-thrusts are imposed on any of the revolving shafts. Special features are, moreover, made of the universal-joints at each end of the propeller-shaft, and of a "spring-drive" device that is introduced between the propeller-shaft and the bevel-gearing for the live axle. The gear-box itself, which—like the engine—is fixed direct to the pressed-steel main frame, is suspended from three points to ensure the necessary flexibility, and the upper half can be taken off independently for

Fig. 4.—Front view of the 12-15.

struction—we now propose, before considering each part in detail, to mention the most striking or unusual characteristics of the new cars. The engine control on both models is an instance in point, for although the power and speed are controlled by a throttle-valve, it admits pure air to the cylinders when the explosive mixture is completely shut off, and although a low-tension ignition system is employed, yet no provision is made for advancing or retarding the spark when running. A novel type of automatic governor, operated by the suction of the engine, has also been devised. Another unusual feature about the ignition system is that no separate cam-operated mechanism is required by the igniters, since the exhaust-valve gear is made to serve this purpose on the twin-cylinder engine, and the rods that actuate the inlet-valves do so on the larger engine; in the latter case, it is true that the time of ignition can be retarded for starting, and that provision is also made for high-tension ignition from a battery, as a stand-by.

Neither engine needs any external lubricator, since the oil is constantly circulated through all the bearings by a special pump, and neither engine has its cylinders

Fig. 5.—The 12-15-h.p. Arrol-Johnston Chassis. Rear view, showing the "Live" Axle.

making a thorough inspection. Similarly, the upper portion of the back-axle-casing is rendered detachable, while, as already mentioned, the road-wheels are mounted outside the ends of the axle-tubes, instead of being merely fixed to the axle-shafts that drive them. The axle is not

—the fan drawing air through the finned-tube radiator in front of the bonnet.

Also specially deserving attention, are the brakes and the steering-gear, both being of unusual and particularly neat design. The former are of the internal-expanding pattern, with easily renewable shoes and a single adjustment screw, while the latter is of the screw-and-nut variety.

petrol-tank is fixed across the centre of the frame, that a curved form of dashboard affords considerable protection to the driver, and that the radiator is built up of horizontal tubes. Also noticeable are the single-lever control above the steering-wheel, and the hooter-bulb that projects up from its centre; as on another well-known make of vehicle, the hollow steering-pillar is utilised for connecting the hooter (in front) with the rubber-bulb.

The 12-15-h.p. Engine.

So compact is the Arrol-Johnston twin-cylinder engine that, even in the two photographs which are given in Figs. 8 and 9, it is difficult to recognise the location of the various parts by merely glancing at it. We therefore reproduce a view showing some of the chief moving members (Fig. 10), and also line drawings of a sectional nature (Fig. 11 and 12). These, taken in conjunction with one another, will be found to convey a good idea of the entire construction.

Fig. 10.—Some of the chief Moving Parts of the 12-15-h.p. Arrol-Johnston Engine.

and can similarly have any back-lash taken up in an equally simple manner.

Both models are shown in our illustrations, the 12-15-h.p. chassis in Figs. 1 to 5, and the 24-30-h.p. chassis in Figs. 6 and 7. Fig. 1 is a view taken looking down from an elevated position on the "off" side, and Figs. 4 and 5 (front and rear views) are also reproduced from photographs. The other figures are line drawings, being side elevations and plans of both cars.

From these illustrations, all the leading characteristics can be gathered, with the assistance of what has already been said, and we can therefore proceed to a more detailed consideration of the more important individual parts. It will be seen, for instance, that the

In Fig. 8, it is seen complete, with the "Hele-Shaw" clutch arranged inside the fan-armed fly-wheel, and in Fig. 9 one of the oil-tight casings, C, has been taken off to expose to view the interior of the crank-chamber, and the mouths of the two cylinders. Both views show it more or less from the right-hand side, but it should be understood that the opposite side is exactly similar. The parts grouped in Fig. 10 include two of the pistons, A¹, the crank-shaft, B¹, the two connecting-rods, C², one of the rocker-castings, C¹, and two of the links, A², that connect one pair of pistons to their rocker, C¹.

There are two main parts—the cylinder-casting, A, and the crank-chamber casting, B. The former is bolted down on the top of the latter, and has flat plates, top and bottom, to complete the water-jacket.

(To be continued.)

THE 1906 LEGROS AND KNOWLES "IRIS" CARS.—PART III.

(Concluded from page 1426.)

The Recharging Dynamo.

VERY ingenious is the arrangement of the dynamo that recharges the accumulators, for not only does it do so quite automatically, but there is no switch mechanism needed for breaking and making the electric circuit. The dynamo itself is specially wound with a demagnetising "series" coil added around the ordinary "shunt" coil upon the field-magnets, and thus the "voltage" of the current generated by it remains practically constant, no matter at what speed it may be driven. It is fixed alongside the crank-chamber on the right-hand side of the engine, and is driven by a flat belt that is always kept at the required degree of tightness by a spring-loaded jockey-pulley. Being completely self-enclosed, no dust can get into the interior, and being quite an auxiliary mechanism on the car, no serious inconvenience would arise even if anything were to go wrong with it.

As already explained, one battery or the other is rendered operative for the ignition system and for the

part rendered clear in Fig. 6, which not only shows the complete apparatus fixed to the branched induction-pipe, A, but includes (on the left) another view in which the inner member, A⁶, of the throttle-valve has been removed, and the float, A⁸, has been lifted out of the float-feed-chamber, A³.

Formed at one side of the float-feed-chamber, A³, is a separate compartment, up through which the petrol has to pass, and this compartment contains a filter—removable with the screw plug, A⁴, at the top. The petrol finds its way into the float-feed-chamber centrally from above, a simple valve—against which the float presses upwards—controlling its flow. Being quite plain, and having no other guiding mechanism, a blind-ended tube is let in to the centre of the float from beneath, and this tube rides upon a fixed pin.

The spray-jet is situated in a small separate chamber, formed solid with the throttle-valve casing, and lies immediately beneath the inspection-plug, A⁵. Into it—from behind, and therefore not visible in Fig. 6—the main-air supply is led direct by a pipe that passes across the engine from the neighbourhood of the exhaust-pipe, and from it into the throttle-valve is the passage, A⁷. The air entering this way passes across the top of the jet, and so becomes carburetted.

The bulk of the air required—except when the engine is running quite light—enters the throttle-valve casing direct from the atmosphere, and is admitted through one port at the extreme top, and a second port exactly opposite the mixture port, A⁷. Both streams, however, come in through the special silencer, A², and both are controlled simultaneously with the port, A⁷, by the moving portion, A⁶, of the throttle-valve. The two streams of pure air are caused to impinge directly upon the stream of carburetted air, by radial funnels, A⁹, inside the moving member, A⁶, and thus they are caused to thoroughly intermingle before passing out beneath into the induction-pipe, A. Such is

the arrangement of the ports that the richness of the mixture is always correctly maintained to suit varying speeds and loads.

One lever—that above the steering-wheel—advances the ignition at the same time that it opens up the throttle. No noise can be made by the connecting mechanism, because flat springs are used in lieu of ordinary hinged joints.

The Gear-Box.

Referring to Fig. 7—which is a view of the opened-up gear-box from above—it will be seen that the lower casting has hinge-lugs, E, at the back, and a swivel-pin, E¹, in front, for enabling it to be secured at these three points to the chassis. The short shaft that is coupled up to the main-clutch has the two ball-bearings, E², and is solid with the wide spur wheel, E³. It also receives the forward end of the driving shaft, E⁴, upon which are the two sliding members. The wheel, E³, is double the usual width, because it serves two distinct duties; it drives the lay-shaft through the large wheel with which

Fig. 6.—The "Iris" Carburettor. On the right, it is shown complete with its Throttle-Valve, Induction-Pipe (A), and Auxiliary-Air Silencer (A²). In the views on the left, the Throttle-Valve (A⁶), and the Float (A⁸) have been removed, and are shown separately.

carriage lamps when the switch on the dashboard is thrown over to either of its "on" positions, and at the same time the idle battery is connected up to the dynamo. Ordinarily, it would, of course, be necessary to fit a special "cut out" in the dynamo circuit to prevent the dynamo from discharging the battery when its speed were insufficient for generating the necessary charging current. Instead, however, use has been made of an aluminium cell such as those now used for converting alternating currents into uni-directional currents, and this serves the same purpose as an automatic cut-out. Without any moving parts, or delicate contacts, the aluminium cell allows the current to flow from the dynamo to the battery, but prevents the reverse action from occurring.

The Carburettor.

Numerous are the unusual minor details in which the Legros and Knowles carburettor, with its throttle-valve, differs from any other. They are for the most

Fig. 7.—View, from above, of the Legros and Knowles Gear-box, with the upper half removed. The three "points" of suspension (E , E' , and E'') are prominent, as also are the ball-bearings on all the shafts. At the time our photograph was taken, the "Reverse" gear was in mesh.

it constantly meshes, and its teeth correspond with those of the internally toothed sliding wheel, E^4 . Thus it is that the lay-shaft is always caused to revolve at a comparatively slow speed, and that a direct-through-drive is obtained on the top (3rd) speed.

§ Also fixed to the lay-shaft, which—like the other shafts—has ball-bearings, are two other spur-wheels, the larger being of the usual width and serving for the second speed, but the smaller, E^6 , being of twice the ordinary width. This smaller pinion, E^6 , is constantly in mesh with one, E^7 , of the intermediate wheels that provide the "reverse" gear, besides being available for giving the first speed forward. There are, it will be observed, two wheels on the intermediate ("reversing") shaft, which lies below the lay-shaft, and the same large

sliding wheel on the driving-shaft, E^5 , thus serves for giving the "reverse" or the first speed—in our illustration it is shown in its "reverse" position.

So clearly shown is the mechanism in Fig. 7 that no further explanation of its action is needed. It will readily be understood that the sliding-rod, E^8 , controls the "reverse" and the 1st speed, and that the other rod, E^9 , introduces the 2nd or 3rd speed. The gear-lever is caused to engage with the one or the other, according as to which of the parallel slots it is caused to occupy in the quadrant. Very simple is the device employed for locking the sliding-rod that is not actually in operation, for this merely consists of a ball dropped in between the two rods inside their guide casting. Both rods have \square -shaped slots that come opposite the ball when the rods are in their neutral positions, and thus the ball is only free to move

sideways from slot to slot when the two slots come opposite; at other times, the operating-rod makes it lock the non-operating rod. All the gear wheels used for the transmission mechanism are made of nickel-steel.

The Universal-Joints for the Propeller-Shaft.

With the special object of eliminating all friction surfaces—except those necessary for giving a slight telescopic action to the propeller-shaft—and of therefore rendering lubrication superfluous, and back-lash impossible, the universal-joints on the "Iris" car rely entirely upon the springy action of steel plates for giving the required flexibility in all directions. In Fig. 8 we give two large views of one of these joints, and also two smaller views of a complete propeller-shaft, fitted with

Fig. 8.—Two large views (from the side and from one end) of the "Iris" triple-plate, Universal-joint, and two smaller views of the propeller-shaft, fitted with these special joints at each end.

them, and think that these illustrations will give an even better idea of the construction than could be conveyed by any written description only.

Fitting over the square ends of the driving and the driven shafts, are the two-armed forgings, F, and at right-angles to them are the corresponding bridge-pieces, F², that are bolted to the propeller shaft by the flanged couplings, F¹. Introduced between the forgings, F and

the adjustable eye-bolt, G⁴, enables the stay to be tightened to the precise extent necessary, and, if taken in conjunction with the fittings at each end of the stay itself, renders it easy to make both halves act equally; the eye-bolt, G⁴, is adjustable from inside the casing, G, and it has a lock-nut outside. The aluminium casting, G, is secured to the axle-tubes by tangential bolts, G², as well as by the clip-bolts seen in the illustration.

Fig. 9.—View, from behind, of the Legros and Knowles "Live" Rear Axle, with the inspection cover—through which the entire Differential-gear can be removed—taken off. The double ball-bearings (G⁷) which carry the Road-Wheel on the outside of the Axle-Tubes are seen in place in this illustration.

F², are the three spring-steel plates, F³, and the two cross-coupling-rods, F⁴, these parts being secured together firmly by rivets and being grouped in the following manner. The first plate, F³, has two opposite corners fixed to the forging, F, only, and its other two opposite corners fixed to the first coupling-rod, F⁴; the second plate, F³, is similarly riveted, firstly to the last-mentioned coupling-rod, F⁴, and, at its other opposing corners, to the second coupling-rod, F⁴; while the third plate, F³, is in just the same way interposed between the second coupling-rod, F⁴, and the forging, F².

By this construction, the power is transmitted through all three plates in sequence, and yet each plate is free to spring sideways if called upon to do so. This freedom of motion in all three plates—alternately at right angles in each—provides the necessary universal motion; the only friction set up in the entire device is purely molecular and is well distributed over a large area. The shape of the plates renders them strong to resist the torsional strains imposed by the engine, and there is practically no tendency for them to buckle.

The Live-Rear-Axle.

Referring to Fig. 9, in which the inspection cover has been taken away, the method adopted for making the aluminium casting and the two steel tubes form a rigid axle is well shown. The lug, G¹, is that to which the torque-rod is attached—this rod relieving the side-springs of all twisting strains—and the three brackets, G³, are those that carry the brake-operating mechanism for both sets of hub-brakes. Also fixed to the outer brackets, G³, is the stay, G⁴, by which any tendency for the axle to sag is eliminated. Stays such as this are well-known in connection with live axles, but it is not always that means are provided for ensuring that they perform their real functions properly. In this case, however,

At each end, the axle-tubes carry the double ball-bearings, G⁷, for the road-wheels, these wheels being therefore mounted quite independently of the enclosed shafts—which merely drive them. No part of the weight of the car is consequently taken by the revolving (or "live") portion of the axle, and a further advantage is derived from the fact that the "live" shafts can at any time be drawn out after the hub-caps have been removed. Flanges are provided on the axle-tubes at each side of that portion (G⁶), that is encircled by the spring-brackets, and, from these same brackets, the radius-rods pass forward to the frame. It will thus be seen that although the radius-rods alone take the "drive" of axle—i.e., it is they that push the whole car when the engine is propelling it—the whole of the tendency that there is for the axle-casing to *revolve* backwards (as a natural corollary to the shafts revolving forwards), is counterbalanced by the central torque-rod.

Of chief interest in the "Iris" axle is that portion of its construction that permits the differential-gear with its bevel-wheel, G⁵, to be taken out for thorough inspection, or for changing the bevel-wheels, without interfering in any way with the casing, G, or the axle-tubes. This is provided for by the straps, G⁶, for the bearings, and by the manner in which these independent bearings are arranged for the outer member of the differential-gear. By taking off these straps, the differential with its bearings can be lifted out complete, provided, of course, that the "live" shafts have been drawn out sufficiently to clear this central mechanism.

Alternative bevel-pinions, with their corresponding bevel-wheels, widely differing in size and gear ratio, are made by Legros and Knowles, for fitting to the car, any pair being easy to fit in place without calling for structural alterations of any kind. Each wheel has the required thickness of collar formed behind it to ensure correct mesh with its fellow.

HIGH-TENSION MAGNETO IGNITION.—PART XVII.

THE GIANOLI SYSTEM.

(Continued from page 1427.)

THE other end of the primary is "earthed" by being fastened directly to the iron core, and it is only through this winding that the secondary coil obtains its "earth" connection. The live-end, C^1 , of the primary coil passes through an insulated bush in one of the end-plates, B^3 , and the live-end of the secondary winding is laid bare, and is coiled up on the face of a soft rubber pad, as is shown in Fig. 5. Pressing against this pad is the large flat end of a steel rod, D^1 , which passes through the centre of the armature spindle, B^1 (Fig. 4), and terminates in a semi-spherical knob at the other end. This rod, D^1 , is, of course, thoroughly insulated from the spindle, B^1 , but the insulation at the extremity is proportioned so that a safety-spark-gap, D^2 (Fig. 5) is formed between a star-shaped steel washer in contact with D^1 and the armature spindle, this being provided in order to protect the armature coil in the event of a fault occurring in the external circuit. The connection between the inner end of the rod, D^1 ,

FIG. 6.—The Gianoli High-Tension Magneto.—Diagram showing how the Magnetic-field, induced by the primary current in the armature core, acts upon the Trembler, C^{14} , which automatically operates the Contact-breaker.

FIG. 8.—The Gianoli High-Tension Magneto.—Views showing the High-Tension Distributor, which is constructed so that it may be mounted on the engine in the same way as an ordinary commutator. This device can also be used with a battery of accumulators; the Contact-maker, N^2 , which is only used for this purpose, is visible in the right-hand view.

and the end of the secondary coil, D , is effected solely by the simple contact between the two members, and a good connection is ensured by the elasticity of the rubber pad. Some connection which shall be easy to

FIG. 7.—The Gianoli High-Tension Magneto.—Diagram illustrating the manner in which the automatic Contact-breaker acts as a voltage regulator by interrupting the current before it reaches its maximum value. After each interruption the current again rises rapidly and operates the Contact-breaker once more—as is indicated by the lines, a , a^1 , a^2 , a^3 —and several successive interruptions are obtained in this way at slow engine speeds. This diagram—which is only based on assumed data—enables these points to be compared for engine speeds of 400 and 1,500 revs. per min., respectively.

undo is, of course, essential in this machine on account of the armature end-plate having to be removed occasionally; the manner in which it is now effected not only provides a coupling of the simplest character, but one which renders the fine wire of the coil end practically immune from the chances of accidental breakage.

The Low-Tension Gear.

The general peculiarities of this mechanism—which, in itself, is the most important of the numerous features of the Gianoli system—have already been mentioned, and only the details of its construction, therefore, remain to be described. The "live" end of the primary winding, which passes through the armature end-plate, B^3 , is secured by a screw to an insulated casting, C^6 , which is prominent in Fig. 5. This casting, C^6 , is placed *outside* the end-plate for convenience in making a connection to

the condenser, as will be explained presently. It is formed with two radial arms, one of them having the hole drilled in it which receives the live end of the primary winding; the other carries the adjustment screw, C^7 , forming part of the contact-breaker, C^3 . This adjustment screw is thus virtually the live end of the primary coil. It projects back through the bearing-plate, B^3 , and against its platinum-tipped end rests the contact point of the other half of the contact-breaker, C^4 . This moving portion of the contact-breaker—which is illustrated in detail in Fig. 5—is made of spring-brass, and it is not, therefore, directly influenced by the magnetism. Its operation depends instead on the action of the separate trembler, C^{14} , which consists of two spring-steel blades carrying a soft iron "keeper" between their upper extremities. Both trembler and contact-breaker are attached by the same screws to the brass end-plate, B^3 , but the trembler is mounted adjacent to the plate, so that in its motion towards the armature—which is made automatically under the influence of the induced magnetism—it will strike the contact-breaker a blow, and thus separate the contacts more quickly than would be the case if the trembler itself made the earthed contact against the screw, C^7 .

FIG. 9.—The Gianoli High-Tension Magneto. — Diagram illustrating the effect of the Contact-breaker in automatically advancing the time of ignition from c to c' , and the counteracting effect of magnetic lag which partly neutralises this advance so that its real value is only from c to c'' .

under working conditions. Our readers are already familiar with the fact that the passage of an electric current, in a coil of wire wound on an iron core, immediately converts the iron into a powerful magnet. Thus then does the armature core become an electro-magnet when the current begins to be generated in the primary coil.

In the Gianoli machine, this magnetism—or at least a portion of it—follows the path indicated in Fig. 6, the iron being specially arranged for it to do so. When, therefore, the primary current reaches a certain value, the magnetism becomes sufficiently powerful to attract the trembler, C^1 , towards the poles, A^2 . In so doing it causes the contact-breaker to interrupt the current, the magnetism, therefore, at once dies down, and the trembler flies back to its normal position; thus allowing the contact-breaker to close again. It is important to notice that the trembler is unaffected by the permanent magnets themselves, because, when the armature is passing through its “neutral” position, practically all the magnetism from the magneto passes through the centre of the armature core which thus “short-circuits” the poles, A^2 . It is, of course, only in the neutral position that the poles, A^2 , come directly under the influence of the permanent magnets.

When the machine is running slowly the current is interrupted several times at each firing point because the trembler is so “set” that the current strength required to operate it is, under all ordinary circumstances, considerably below the “maximum.” At very high engine speeds there is less time for the trembler to operate, and the interruptions of the primary current are fewer in consequence. This is diagrammatically illustrated in Fig. 7, in which two curves representing the fluctuations in the magnetising force of the armature at speeds of 400 and 1,500 r.p.m. respectively, are shown. At the slower speed, the magnetising force, which is re-

The soft-iron “keeper” of the trembler is mounted so that it is always opposite to the two small pole-pieces, A^2 , on the armature core and it is these which attract the trembler at the right moment. The manner in which the poles, A^2 , become energised will be easily understood by reference to Fig. 6, which shows diagrammatically the magnetic circuit formed

presented by the line, a , rises with the increasing voltage of the armature, until it attains a certain value represented by the height of the line, b , above zero. At this instant it is sufficiently powerful to attract the trembler, and simultaneously, therefore, the circuit is broken, and the magnetising force ceases to exist. Almost immediately, however, the circuit is closed again, and the magnetising force, a' , quickly rushes up to its active value once more, and so operates the trembler again. This, it will be noticed, occurs four times—according to the diagram, Fig. 7—at 400 r.p.m., but only twice at 1,500 r.p.m. But these values are only assumed for the purposes of explanation.

The trembler must essentially take a certain interval of time to vibrate, even once, to and fro, and as this interval is of fixed duration for any particular trembler, it consequently represents a larger proportion of a complete revolution at high, than at low, speeds. This point is graphically illustrated, in Fig. 7, by the relative slopes of the lines, c , c' , in the left and right-hand diagrams; and it is this which accounts for the fact that there are fewer interruptions at the higher speed.

The dotted continuation of the curves, a , represents the values which the armature current would reach if it were not interrupted along the line, b . It also graphically illustrates the effect of the trembler in automatically regulating the strength of the induced voltage, and, by so doing, protecting the insulation of the winding from excessive electrical strains. It will be noticed that in the right-hand diagram of Fig. 7 the line, b' , is drawn higher up than it is on the left. This is due to the fact that the magnetism lags somewhat behind the current producing it, which consequently attains an increased value at higher speeds before the trembler is operated.

The Condenser.

The condenser is contained in a specially-shaped aluminium case, F^1 , which is secured in place between the magnets, in such a way that it forms an arch over the armature, which it thus shields from dust. The connection to the live terminal on the condenser is made by a brass strip, F^5 , which presses lightly against the casting, C^6 . In the new models, however, this method will be altered and the casting, C^6 , will be replaced by a slip-ring, and the brass-strip, F^5 , by a carbon brush. The other side of the condenser is, of course, “earthed” in the usual way, so that it is electrically-connected across the contact-breaker, C^3 .

(To be continued.)

FIG. 10.—The Gianoli High-Tension Magneto. — Diagram of the Internal Electrical connections showing the Magneto system by itself. Battery and coil ignition can also be used as an auxiliary, but the wiring for this is shown in Figs. 13 and 14.

THE STANLEY SHOW.

THIS year the 29th Annual Stanley Show, which was opened at the Agricultural Hall by Sir Albert Rollit, M.P., on the 17th inst. and closes to-day (Saturday), appears to have recovered its position as a purely cycle exhibition. It is true there are still a certain number of motor vehicles, ranging from the motor bike to 5-ton steam lurry, but, as a class, they are not nearly so much in evidence as they were last year. This may be

Another new car is the "Kelvin," shown by the Century Motor Company, while the East London Rubber Company show the "Kerry" car, and the Civil Service Motor and Cycle Agency exhibit new models of the Pope-Tribune cars, for which they have the English agency. On Brown Bros.' stall, a two-seated doctor's brougham—with steering-wheel and control-levers inside the body—was shown alongside one of their standard 18-20-h.p. touring vehicles. Besides the 9-h.p. dog-cart, which is, perhaps, the best known of their standard models, Messrs. Jackson also exhibit a much larger car, fitted with a 16-h.p. four-cylinder engine.

There is a marked falling off in the number of motor cycle exhibits. Tri-cars are not nearly so numerous, and at least one well-known firm has entirely dropped the manufacture of these small machines. It is significant, too, that one of the most important firms still building tri-cars should have decided to adopt the extra wheel for their higher-powered models. This entails using a differential gear on the back axle, which means additional expense in construction, but it eliminates the most important drawback to the other type.

On the whole, however, we do not see that it possesses any great merits as a new type of machine, for while being now virtually a car as regards number of parts, it is still little better than a tri-car considered as a vehicle.

Apparently the extremely powerful motor cycles of last year have not met with unstinted appreciation, for

STANLEY SHOW.—The latest evolution of the tri-car! A four-wheeled vehicle, constructed by Phoenix Motors, Limited, which has the tandem seating peculiar to tri-cars. Just behind the front seat is a twin-cylinder engine from which the power is transmitted, by a chain, to a two-speed and "reverse" gear, of the epicyclic type, mounted on a countershaft. Another chain is used to drive the differential gear on the live axle.

accounted for by the fact that the Olympia Show is now also in full swing, so that as far as motor-car exhibits are concerned only those few firms who failed to secure space there are exhibiting at the smaller show, where they are mostly to be found in the "Minor" and "King Edward" Halls. Most prominent of these is the Hummer Company's stall, where no less than four cars and two chassis are on view. It is an even better exhibit of these popular vehicles than is to be seen at Olympia, where, as a matter of fact, the general reduction of space has only enabled them to show two complete cars. This year they are making only two standard models, viz., 10-12-h.p. and 16-20-h.p., both of which were on view, one model in particular—a five-seated double phaeton—being especially noticeable for its handsome finish.

An entirely new model, fitted with a four-cylinder 10-h.p. engine, is shown by the Star Engineering Company, who also exhibit their standard 7, 14, and 18-h.p. cars. On another stall is the little Starling car—first introduced last year—which has been exalted to the possession of a three-speed-gear-box and ball-bearing hubs. Taking the place of honour among the Corrê exhibits is the car which carried "General" Booth on his missionary tour last August. Under the imposing name of the "British" car a new vehicle is introduced to the public by the British Motor and Engineering Company. It has some unusual features, notably the radiator and the arrangement of the starting handle on the dash, and it is also fitted with a Fafnir engine.

STANLEY SHOW.—The Bentall Engine—exhibited by the Crypto Company—in which compactness is the ruling feature of the design. It has the ordinary mechanically operated valves, but instead of arranging the valve chambers on diametrically opposite sides of the cylinders, they are set at an angle in order to bring the cam-shaft closer to the crank-shaft.

the majority are now of more normal power, although there are still a few twin-cylinder machines, and three firms are even showing four-cylinder engines.

On the stand of the Crypto Car and Cycle Co. is a new engine, which we illustrate, and in "King Edward's" Hall, the Lloyd's Roller change-speed-gear—which was

fully described in our issue of the 4th inst.—is shown in operation. Quite an important exhibit of component parts was shown by Messrs. Gauthier and Company, the well-known agents for the new Bassée-Michel high tension magneto, which recently formed the subject of a special article in our columns.

CORRESPONDENCE.

THE NEW TOURIST TROPHY REGULATIONS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—All open-minded automobilists will be glad to see that the Automobile Club propose to admit steam cars to the great automobile event of the year, under conditions which will give steam cars a chance of finishing the course which is set before them.

The Automobile Club, however, propose to give steam cars considerably more fuel than is allowed to petrol cars, and steam cars are to be given the opportunity of winning the Trophy on an allowance which is admittedly arbitrary.

The foundation of the Tourist Trophy Race was that all cars should have the same fuel allowance, and that the car which is most efficient should win. The proposal of the Automobile Club destroys the whole foundation of the race, as the suggestion is that an admittedly inefficient car may win the Trophy, and the public will only recognise the bare fact that a steam car has won it, and will overlook the important factor that the car had an extra allowance of fuel on account of its inefficiency.

I sincerely trust that the Committee will re-consider this matter, and will revert to the foundation of the race, viz., an equal quantity of fuel for all cars, and the most efficient car wins.

Would it not be preferable that a special cup should be instituted or steam cars, to be run for at the same time and over the same course as the race for the Tourist Trophy, and that the allowance of fuel for the steam cars shall be the same as the allowance of fuel for the petrol cars, but that the course for the steam cars shall be 137½ miles long, as compared with the course for the petrol cars of 208½ miles long.

The steam cars would have lots of sport one against the other, and there would be no danger of the public being misled into believing that in an efficiency race the steam car can win a Trophy from a petrol car.

I am, Sir,

120, St. James Court, S.W.
November 10th.

Yours obediently,
C. JOHNSON.

SPECIAL ROADS FOR MOTOR CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I see a lot of nonsense has been written about the building of special roads, and now I hear that a Bill is to be presented to Parliament to permit the construction of a special road, for motor car use solely, between London and Brighton. Of all the silly schemes that have been evolved in connection with motor cars, I think this is the most stupid, and the promoters deserve to burn their fingers over it. At the present time there is sufficient agitation against cars, and the proposal to construct special roads is only giving the other side a substantiation of their opinion that motor cars are not safe on ordinary roads, and that they should be limited to roads specially built for them, which would deprive motoring of its utility, and of nearly all its pleasure. What, I ask, would be the pleasure of driving along a road, which would be as straight as possible, and without a gradient worth calling such? It will merely devolve into a scorching track, and, in all probability, will be so badly handled that the authorities will be called in to control it. I only hope that the Automobile Club will do its best to oppose the Bill, if it gets to that stage.

Yours faithfully,

Coventry, November 10th. ERIC W. WALFORD.

6-CYLINDER ENGINES.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I have read with great interest Mr. Edge's arguments in favour of 6 as against 4-cylinder engines, and I must say that I have yet to be convinced that the additional complication of two more cylinders is an advantage.

I readily admit that there are a number of points in favour of the 6-cylinder engine, but at the same time there are a considerable number of disadvantages.

Mr. Edge points out that the fly-wheel on a 4-cylinder engine has to be double the weight of the fly-wheel on a 6-cylinder engine to secure the same smoothness of running. Admitted that this is the case, surely it does not count as a disadvantage, as obviously the extra weight of the two additional cylinders in the 6-cylinder engine is considerably more than the extra weight in the fly-wheel, which would, under Mr. Edge's arguments, be necessary in the 4-cylinder motor.

I also note that it is admitted that the 6-cylinder engine, by reason of the loss of 18 per cent. in wall heat, is less efficient than the 4-cylinder engine. Surely this considerable percentage of loss does not suggest that the 6-cylinder is weight for weight more efficient.

Another point on which some interesting information might be obtained is in regard to petrol consumption. I am informed that the extra amount of fuel consumed is not compensated for in any measure either by power or hill-climbing capabilities, and as, at the present time, we are in England encouraging competitions similar to the Tourist Trophy Race, which are arranged with the sole idea of encouraging the construction of cars to give the best results on the minimum quantity of fuel, it seems somewhat retrograde to advocate a type of engine which is necessarily extravagant.

Again, at the present time, there is an inclination on the part of the buying public that cars should not be made with an abnormal wheelbase; at the same time luxurious carriage bodies are required with wide and roomy side entrance doors, and therefore a certain length behind the dashboard is absolutely necessary. If, in addition to this, the front wheels are carried out a long way in front of the dashboard, which is necessarily the case with a long 6-cylinder engine, a car of abnormal wheelbase is the result, which is not only unwieldy to drive in traffic, but is at the same time difficult to handle on narrow roads and round corners.

One has only to see the lengthy bonnets fitted to 6-cylinder motors to appreciate this point, and I cannot help but think that eventually users of cars will put this forward as a serious disadvantage when the merits of the two types are seriously considered.

In regard to silence and flexibility, there are 4-cylinder motors which will stand comparison with the finest 6-cylinder engine yet made on both of these points, and, while mentioning this matter, I would suggest that the fact that a 6-cylinder car has been able to achieve something just over 20 miles an hour at a 1,000 revolutions per minute does not make such a car more practical in the hands of an ordinary user than a 4-cylinder car of the same horse-power geared to the same ratio.

Yours faithfully,

November 13th.

CHAS. JARROTT

SPRING WHEELS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Just now the automobile Press and the general Press seem to be pretty busy publishing accounts of new spring wheels, and, judging from the newspaper accounts, it would appear that the pneumatic tyre is doomed. Now let us take an example of the usual spring wheel, and consider what really happens in the case of the driving-wheels—the tyre being solid, mounted on a steel rim with the springs between the rim and the hub. If, say, the car goes over a two-inch high obstacle and the spring wheel absorbs all this, then the distance between the hub and driving surface is two inches less, that is equal to a wheel four inches less in diameter. So, that is to say, when the spring wheel is in use, it is constantly altering the gear of the car, which all means loss of power together with the moving parts in the wheel.

The great beauty of the pneumatic tyre is that it glides over all minor obstacles without perceptibly varying the distance between the hub and road surface, the larger variations being taken up by the springs between the axle and car body, this latter case also applies to spring wheels.

So it will be seen that it is immaterial whether the springs are placed between the rim and hub or between the hub and body of car, the latter being the correct place.

47, West Hill,
Wandsworth, S.W.

Yours faithfully,

A. VERDON ROE.

SPEED INDICATORS FOR AUTOMOBILES.— PART VIII.

THE VEEDER TACHOMETER.

THE Veeder Tachometer was one of the earliest speed indicators to be put on the market. In fact, our first description of it appeared so long ago as April 18th, 1903, and yet the apparatus—for which Messrs. Markt and Co. have the English agency—has altered but little, even in detail, since that date.

For automobiles the Veeder Tachometer is an adapted form of a similar instrument which has a far more extended and longer-established utility in the engineering world, as an indicator for showing the speed of engines and machinery shafting. There is no difference in principle between the two models, however, for the modified instrument has merely been constructed in two independent parts, instead of as a complete unit, in order to allow the active

member to be situated close to the road-wheel which drives it, while the dial portion is mounted separately in some convenient position on the dash. Our illustrations show both forms: Figs. 1 and 3 being photographs of the engine tachometer, while Fig. 2 is a sectional line drawing of the apparatus designed for motor cars.

In principle the Veeder Tachometer belongs to the hydraulic type of instrument, for its active member is merely a simple centrifugal pump, while the indicator proper is only a gauge-glass containing the column of liquid thrown up by the rotation of the pump. No actual circulation takes place, because the gauge-glass is too high for the capabilities of the pump, which maintains instead a "head" of liquid, the height of which is proportional to the speed at which the pump is driven.

In the engine tachometer, Fig. 1, the pump is contained in the base of the instrument, whereas, in the automobile model, Fig. 2, it is separate—being connected to the gauge-glass by flexible tubes. The gauge-glass, A, is mounted above a small chamber, B, forming a reservoir, and is supported in position by a framework of which the principal members are the three vertical rods, E, and the bracket, E'. Alongside the glass, A, is a scale, A', calibrated either in miles per hour, or revolutions per minute, as the case may be, and behind this is the overflow pipe, B', which communicates with the top of the gauge-glass by means of the passage, E'. Should, by chance, the speed become abnormal, so that the liquid rises to the top of the glass, A, the tube, B', is then available for returning any overflow direct to the reservoir, B.

The pump, C, is shown on a larger scale in Fig. 3, and its simple construction will be obvious from this view. It is merely a paddle-wheel, C', mounted on a spindle, C², the whole being enclosed in a close-fitting, water-tight case, C, with one end of the spindle, C², which is carried in ball-bearings, projecting out so that it can be driven by a chain sprocket, or pulley.

The liquid contained in the reservoir, B, finds its way through the pipe, B², to the centre of the pump wheel, C', and, as the pump revolves, it is thrown outwards by centrifugal force, and rushes up the pipe, A², which communicates with the gauge-glass, A. As the liquid rises in the gauge-glass, its weight reacts on

Fig. 2.—The Veeder Tachometer. — Sectional drawing of the motor-car type of indicator, in which the pump mechanism is entirely separate.

Fig. 1.—The Veeder Tachometer.—Views showing the instrument complete. When used for motor cars, the lower part of the instrument, containing the pump, is made separately so that it may be fixed near one of the front road-wheels of the car. The type illustrated is used for indicating the speed of engines and other machinery.

the pump, and when it reaches a certain height—dependent upon the speed at which the pump is being driven—its “head” (i.e., downward pressure due to height) counterbalances the upward lift of the pump, and the liquid then comes to rest.

The “head” of liquid capable of being supported by the pump varies as the square of the speed, consequently the scale is much more open at the top than at the bottom, and its effective range is limited to about one-fourth its maximum.

In all mechanical details, these instruments, which are made in America, are well designed, and most carefully constructed. The pump-spindle runs on ball-bearings, and every convenience is provided for setting, fitting, and testing the indicator before use.

For this purpose there are three cocks on the outside of the reservoir casting. The main valve, D, is a four-way cock, marked with the letters “F. C. T. and W.,” which correspond with its four positions of “Filling,” “Circulating,” “Testing,” and “Working.” In the engine tachometer, Fig. 1, the valve, D, is not a four-way cock but merely a straight-through valve to check the speed whilst running.

In front of the reservoir is a set-screw, D², for making minute adjustments to the zero level, and on the other side is a drain-cock, D¹, for drawing off superfluous fluid. When filling the instrument, liquid (coloured alcohol) is poured in through the top of the tube, B¹, which has a screw cap for the purpose, until it reaches the zero level in the gauge-glass. The level in the reservoir, B, which can be observed through the glass window, B², should

be about $\frac{1}{16}$ inch below the level in the gauge-glass, on account of the capillary attraction in the latter. If the difference is more than this, it indicates that air still remains in the pipes, and this should be expelled by turning the cock, D, to the “circulating” position and driving the pump.

When the zero has been finally set by the use of the fittings, D¹ and D², the valve, D, is turned to its working position and the indicator is ready for use. In the instrument, illustrated in Figs. 1 and 3, the lower edge of the cone, A², indicates the zero level to which the liquid must be set.

By turning the valve, D, to the “circulating” position whilst the pump is running, the liquid in the gauge-glass will be retained in its position indefinitely.

The “zero” can also be tested when the car is running by turning the cock, D, into the “testing” position.

These instruments will, we understand, be exhibited at Olympia on the stall of the United Motor Industries, Limited.

Fig. 3.—The Veeder Tachometer.—View on a larger scale, showing the pump, C¹, in place in the interior of the pump-chamber, C.

MESSRS. S. SMITH AND SON, of the Strand, who have done so much for the production of accurate speedometers, are very naturally gratified with the splendid testimonial that has been provided to the accuracy of their chronometer work by Captain Scott's explorations on the Antarctic Continent. It appears that his ability to determine his position on the great plain or plateau of the interior entirely depended upon the accuracy of one of Smith's timekeepers, with which he was provided. It is a remarkable circumstance and a caustic commentary on “justices' justice” that accurate scientific instruments of the speedometer type constructed by a firm thus renowned for accurate workmanship are treated with the most supreme disdain by magistrates of the “Handover” class when the speeds they indicate are in conflict with the interested statements made by police constables.

RACES, RECORDS, AND TRIALS.

On Saturday, September 16th, the motorists and cyclists of Christchurch, New Zealand, organised a monster run by way of emphasising their demand for better roads. Over 2,500 took part in the procession, the destination of the run being the Metropolitan Trotting Grounds, where the event was made the occasion for an interesting motor gymkhana. In our photographs above, which are from the "Canterbury Times" (N.Z.), the picture on the left is that of Mrs. G. Sutherland, on her Wolseley car, who was winner of the ladies' driving competition at the gymkhana. The right-hand picture shows an interesting contest in the programme, arranged between a motorist and a cab-driver, for testing the stopping capabilities of the two vehicles while travelling at a smart pace. Needless to say the motorist won easily.

4,000 Miles Tyre Trials.—The full regulations of these trials, which are being organised by the A.C.G.B.I., have now been issued. The objects of the trials are to test the durability of standard types of tyres, taken from stock by the club, and their ability to run long distances without involuntary stops, and to ascertain and record their behaviour and the time occupied in replacements or adjustments. The trials are to be carried out as far as possible under ordinary touring conditions, and the competing tyres are to be fitted to ordinary touring cars as sold to the public, each entrant providing suitable cars for the purpose. The club reserves to itself the right to refuse or return any entry without giving a reason, and the trials will not be held unless a minimum of five sets of tyres are entered on or before January 3rd, 1906. The fees chargeable will vary according to the number of sets of tyres entered, as follows:—

5 to 10 sets	Fee £100 per set of tyres.
10 to 15 "	" £75 per set of tyres.
15 to 20 "	" £60 per set of tyres.
20 to 30 "	" £55 per set of tyres.
Above 30 sets	" £50 per set of tyres.

There are 9 classes, as follows:—

PNEUMATIC TYRES.

	Minimum Total Running Weight.	Passengers.
Class A. Light cars	1,500 lbs.	2
" B. Medium cars	2,400 "	4
" C. Touring cars	3,000 "	4
" D. Heavy cars	4,500 "	4

No tyres in these classes may be fitted with any device which protects the tyre from wear. A set of tyres in these classes means 4 tubeless pneumatic tyres or 4 outer covers and 4 inner tubes.

ARMoured PNEUMATIC TYRES.

Class E.	3,000 lbs.	4
-----------------	------------	---

This class is limited to a combination of tyre and armoured protective device, and a set of tyres in this class means 4 inner tubes and 4 covers, each with protective device.

SOLID RUBBER TYRES.

Class F. Light vehicles	1,500 lbs.	2
" G. Medium vehicles	3,000 "	2
" H. Delivery vans, &c.	6,000 "	2
" I. Heavy vehicles... ..	14,000 "	2

In these classes a set of tyres means 4 solid rubber tyres, or 6, if double tyres be used on the back wheels.

No form of spring road-wheels may be used in these trials in any of the classes. Competitors will be permitted to use additional tyres, covers, inner tubes, or protective devices, if selected before the trials and marked by the club, provided such parts as are replaced are handed over to the club as being worn out. The tyres will be under the control and observation of the club throughout. Competitors may at any time terminate the trial or any particular entered set, but must state the reason of withdrawal. Upon the withdrawal or failure of any set of tyres they shall be removed from the wheels, if required, in order to satisfy the observer as to the actual cause of failure.

The air pressure of pneumatic tyres will be tested at the discretion of the club, and tyres must only be run at a pressure not exceeding that declared by the entrant when entering.

The trials will commence on February 1st next in or near London, and will be over a distance of 4,000 miles, but if, at the conclusion of this distance, any competitor desires to continue the trials for his tyres, he may arrange to do so at a fee of £2 per set of tyres per day. Two hundred miles per day will be the maximum run, and each day's run must be completed within a period of 36 hours, or the tyres will be deemed to have been withdrawn. This time limit, however, does not apply to delays caused by failures other than tyre failures. As far as possible, the main roads will be followed, and if the whole route for the day is not completed on the day by any car, it must be completed over the same route on the following day. Speed will be carefully regulated, especially in towns and villages. All involuntary stoppages caused by failure of any part of the tyres, or for adjustment or repair of the tyres, will be recorded, voluntary stops authorised by the Observer not being noted. Engines may be stopped while running downhill or during stops. Adjustments and repairs may only be carried out by the driver and mechanic, both of whom may be changed by consent of the Observer.

The award offered in each class for the set of tyres making the most meritorious performance is the Club's Gold Medal, and for the second best a Silver Medal.

In making the awards, the size, weight and price of the tyres in relation to the weight carried will be taken into consideration. Each competitor will receive a certificate of performance, and a Special Trophy will be given in Class D, if the performance of any one set of tyres is considered sufficiently meritorious.

The Tourist Trophy.—In regard to the proposal to make a special award to cars of entirely British manufacture which took part in the Tourist Trophy Race, as several queries have arisen as to the action of the Club Races Committee in this matter, possibly it has been forgotten that as long ago as March last a resolution was passed by the Club Committee that such an award should be made, the conditions being that the cars should comply with the Gordon-Bennett rules so far as the country of origin was concerned. The handling of the matter was at the same time referred to the Races Committee to consider to which car or cars such awards should be given, and they are, therefore, now only following out the terms of this resolution, which was published about the date of its being passed, viz., March 6th.

Middleton's Pneumatic Hub—A 4,000 Miles Reliability Trial under the auspices of the Automobile Club started on Tuesday morning last, the 21st inst., for the purpose of testing the merit of the Middleton Pneumatic Hub, which was described in our last issue. The car to be used in the test is an 18-22-h.p. Rochet-Schneider.

American Economy Test.—In connection with the economy test, held under the auspices of the New York Motor Club, of which we gave the outline some time ago, particulars are now to hand of the results. Nine cars started over the prescribed distance of 700 miles. Of these, 7 finished, the 16-h.p. Reo omnibus, carrying 10 passengers, winning the trial, and an 8-h.p run-about of the same make coming in second. The winning car carried its passengers the full distance at under 12s. per head. By way of comparison, the railway fare for this distance would have been £2 18s. per head. The competing vehicle showing the least economy of the seven classed cars, shows a cost per head of about 18s. Fuel and lubricants used during the run, adjustments and repairs made to the machine, in addition to ferry tolls, were included in the total costs. In this respect, the Reo 'bus was charged for mechanical troubles about 19s. A protest was entered against the winner upon the ground that the passengers dismounted and walked up a hill on the Albany Road. This, however, was held not to affect the position, a charge having been made against the vehicle of 2½ dollars for the walking episode. The following table gives the results in tabular form of the cars which finished:—

Place.	Car.	Passengers.	Cost.				
			Gasoline.	Oil.	Total.	Per Pas.	Per Mile.
	h.p.		\$	\$	\$	\$	\$
1	16 Reo 'bus...	10	16.00	3.38½	29.30	2.93	.42½
2	8 Reo	4	7.99½	.25½	13.54	3.38½	.49½
3	15 Compound	5	10.87½	2.12	18.62½	3.72½	.54½
4	20 Wayne ...	5	12.40½	2.10	19.81½	3.96½	.58
5	8 Olds	4	10.35½	.42	15.86	3.96½	.58
6	15 Compound	4	10.34½	2.13	17.18½	4.29½	.62½
7	20 Marmon ...	5	14.82½	1.140	22.91½	4.58½	.67½

Flying Kilometre Record.—In respect to the note which we gave last week regarding Dufaux's time for the flying kilometre at Ostend, we stated that unofficially Baras had been timed with 21½s.—world's record time—in 1904 over the distance. Messrs. A. Darracq and Company write us, in regard to this statement, that Baras' record on his Darracq car was timed by the official time-keepers of the A.C. de France, and that the record has been recognised generally throughout the world as tying with that made by Clifford Earp on a Napier racer this year at Blackpool. This is perfectly correct, but, at the same time, we also understand that, magnificent performance as that of Baras was—a performance which no red-tapeism or officialdom can do away with—that when the time was recorded, unfortunately the Ostend Road was not officially classed by the A.C. de France as a road on which attempts on the world's records for speed could be made. Later it was laid down by the Club that if Baras desired to have the time entered officially upon the Club record, he must make two runs, one each way, the average time being then recorded. This unfortunately has not yet been done, and although his record time of 21½s. was absolutely authenticated in 1904 by official timers, the A.C. de France have not so far, we believe, placed the record on their books.

Florio Cup.—For 1906, some modifications are announced in the rules for this race in Italy. Entry of cars of any one make is to be limited to four, to include one reserved for entry by a private owner. The circuit will probably be shortened so as to avoid as far as possible railway level crossings.

M. TAMPIER, the well-known official timekeeper of the A.C. de France, has now officially retired from his post. His resignation was received with much regret last week by the French Club, and a formal communication of regret has been made to M. Tampier by the Club.

Kiel Regatta.—The motor boat events during the Kiel Regatta next year are announced to take place on June 28th and 29th. On the first day the races at Kiel will be held, and on the second the long-distance run from Kiel to Travemünde.

THE Mediterranean Cup for motor boats is to be again run for in 1906, the points being from between Toulon and Palermo.

English Cars for the Continent.—We understand from Mr. S. F. Edge that he has just fixed up a contract with M. Fournier to supply £59,400 worth of 6-cylinder Napier cars for the French market. M. Fournier—who has now been joined by Baron de Caters—represents the Palais Automobile, one of the most important automobile centres in Paris, so it is exceptionally good news that a start, right in the centre of the rivals' camp, should be about to be made under such auspicious circumstances.

It has not hitherto been public property that another contract of considerable magnitude has been arranged for Italy with a company which has already been formed there.

The Police and the Automobile Association "Scouts."—The police seem to be sharing our view that to proceed against the scouts of the Automobile Association (who are, after all, only endeavouring to prevent breaches of the law) for obstructing the police in the discharge of their duty, is not only indefensible legally, but likely to make the police themselves look even more absurd than the pigstyes and "umbrageous thickets" of the Ripley Road have succeeded in doing. So one of them has been charged with perjury by the police manning the trap which he "scouted" on the Fairmile near Cobham, and Superintendent Marks and some of his men gave evidence against him before the Kingston-on-Thames Bench on Saturday last, which resulted in his being committed for trial at the Guildford Assizes. The unfortunate "scout" in question was arrested on a warrant on Saturday, and not allowed to communicate with his friends till the Monday, nor was he brought before a magistrate so that he could have been admitted to bail, by which means the police succeeded in at any rate imprisoning him effectively for two days. The police deny that they were actuated by malice in the matter, but if it had been any other sort of case does anyone suppose that they would have arrested a man, whose address and whereabouts were well known, on a bailable offence, at a time and under circumstances when there was practically no possibility for his being bailed out? Under the circumstances they may deny malice, we think, as much as they like. That they do not feel their position a proud one is shown by a snapshot, which we reproduce above, of two of the police officials who gave evidence in regard to the alleged perjury. One of them, it is true, is laughing as if he thought the whole thing a good joke, but the other, observing the photographer, has raised his polically mantle so as effectively to obscure his countenance. He, at any rate, was not going to have his physiognomy permanently associated with tactics of this kind—small blame to him for that same.

Andover Redivivus.—We hear from the Automobile Association that the police-traps on the Andover Road are by no means abandoned, as we had been previously led to suppose. On the contrary, the trap three miles on the London side of Andover at Fox's Farm, and the other equally notorious arrangement of the same kind nine miles further on, were in full working order on Saturday last. The scouts of the Automobile Association, however, performed their duties most efficiently, and we believe the police quite failed to make a bag. The recent utterances, therefore, of the local police must be regarded as an artful attempt at laying of false scent for the Association scouts—the police evidently not wishing to share with others the credit of preventing law-breaking.

THE Founder Members' Dinner of the Automobile Club is announced to take place on December 6th at the club.

Hyde Park and Automobiles.—His Majesty's First Commissioner of Works, has notified his intention that next summer the restrictions imposed in regard to the admission of automobiles to Hyde Park will be rescinded as far as electric vehicles are concerned. It will be remembered that the point was brought before Lord Windsor and Lord Balcarras last year and that they then refused to make an exception in favour of the electromobile, owing to the difficulty of distinguishing them from some petrol-driven carriages.

The Police and the Automobile Association's "Scouts."—A snap-shot of two of the "police-trappers" who are witnesses in the case of alleged perjury at Kingston-on-Thames against "Scout" Jones, who has helped the police so much in preventing motorists from inadvertently exceeding the speed limit. The style of standing up to the camera of the second constable is probably a reflection of the habit of being concealed in hedges and pigstyes.

Royal Commission on Motor Cars.—The new witnesses who have given evidence before the Royal Commission since our last issue, include the following:—Mr. S. Stallard, Clerk to the Warmley Rural District Council; Mr. Seymour Williams, County Surveyor of Oxfordshire, representing the Rural District Councils' Association; Mr. Kidner and Mr. Biddell, representing the Central Chamber of Agriculture; Sir William Chance, Bart., Chairman of the Guildford Bench; the Hon. Sir Schomberg M'Donnell, K.C.B., Secretary of His Majesty's Office of Works; Major-General Benson, C.B., Director of Transport and Remounts, and Major F. Lindsay Lloyd, R.E., representing the War Office; Lord Montagu of Beaulieu; Mr. J. A. Bean, County Surveyor of Northumberland; Colonel Crompton, C.B., and Mr. E. S. Smith, representing the Motor Van and Wagon Users' Association; Mr. Breathwaite and Major Creagh, representing the Elstree Parish Council; Mr. H. P. Maybury, Kent County Surveyor.

VERY enjoyable was the excellent banquet at Prince's Restaurant, last week, which the Daimler Company gave to a few representatives of the Press. Sir Edward Jenkinson, the Chairman of the Company, presided. The after-dinner remarks were, in the main, of quite an unorthodox character, amusing tales without number being a feature of the evening, these being largely contributed by Mr. Charles E. Hands, Mr. Frederic Coleman, Mr. Massac Buist, and a few others.

The loyal toasts disposed of, Sir Edward Jenkinson gave the toast of the evening, "Our Guests," and maintained that by the use of experts and the adoption of scientific and up-to-date methods nothing was to be feared by English manufacturers from foreign competition. The results of this policy he had earlier in the week had the pleasure of explaining to the shareholders in his Company when the very splendid balance-sheet which had been produced was welcomed by the shareholders and all interested in the automobile industry. Conservative and insular self-satisfaction with old

CLUBS AND ASSOCIATIONS.

The British Empire Motor Trades Alliance.—The following firms have been elected to membership:—Dean and Burden Brothers, Limited, Salisbury; Lanchester Motor Company, Limited, Birmingham. Associate membership:—Avon India-rubber Company, Limited, Melksham; Electric Ignition Company, Limited, Birmingham; Hooper and Co., Limited, London.

Ladies' A.C.—It is pleasing to see that the Ladies' Automobile Club are recognising the importance to lady automobilists of being thoroughly acquainted with all the details of their cars from an engineering point of view, and the greatest interest has been shown by the members in the practical lectures on the working parts and engineering terms of cars which are now being given at the Club. The course of lectures deals with such practical matters as the history of radiators, pumps and silencers, accompanied by practical demonstrations with the latest types of engines, and the fair automobilists give the very greatest attention to making themselves thoroughly conversant with the working of the various parts. We have always insisted upon a practical knowledge being essential for everyone who desires to be an effective car driver, and the extent to which the ladies of the Ladies' Automobile Club are realising the situation is a further demonstration, if any were needed, of the truth

The above photographs giving some interesting views in Queensland have been sent us by MR. FRANK W. INSTONE, who has, during the past twelve months, been in Australia in connection with automobile business and has travelled and examined long distances of the roads in the interior. In various districts the roads he reports to be good, on the average, but in more remote parts of the country they are quite unsuitable for motors, but Mr. Instone is confident there is a big future for cars in the Colony and that suitable motor boats promise an enormous field for business. In our central picture, Mr. Instone is seen on a "hippomobile" on which he did some of his prospecting. On the left, a 32-bullock team is shown drawing timber, this scene giving an idea what automobiles have to replace in Queensland. In the photo on the right, Mr. Instone is skirting a mangrove swamp.

methods he thought was the main trouble in most cases of non-success in this country. All the protection in the world would not make the public buy bad goods.

Mr. Percy Martin, the engineer responsible for the high-class work turned out by the Daimler Company, gave a practical and instructive speech upon industrial tendencies in the automobile world, which was received with considerable appreciation. Mr. Martin proved himself to be a very strong advocate of the principle that it was better to sell 1,000 cars cheaply than 500 at a higher price, as every good car that was put on the road became an advertisement, and therefore the larger the number, the more friends were made.

THE Caledonian and London and North-Western Railways have inaugurated a new express goods service between Glasgow and London, as a result, it has been stated, of the recent record run in conveying a consignment of Argyll cars for Argylls, London, Limited. The journey is now being accomplished in ten hours.

that the automobile movement is producing a widely-educative effect.

Leicestershire A.C.—The headquarters of this club are now at the Grand Hotel, Granby Street, Leicester.

Motor Yacht Club.—The club has obtained the charter of the late Admiralty yacht "Enchantress," which will be used by them for the purpose of a floating club-house on Southampton Water. This roomy vessel is eminently suitable for the purpose, as she is already fitted with a large number of state rooms and ample saloon accommodation.

Sheffield A.C.—A special general meeting is being held on Monday next of members of the club, to consider the question of holding a motor car show in Sheffield, and for the presentation of challenge cups and medals won in the hill-climbing competitions.

MR. J. A. MACKLE read a paper on "Air Cooling for Petrol Motors," at the opening meeting of the second sessions of the University of Liverpool Motor Club last week.

AT Plymouth, the South Devon Automobile Club was formed last week.

The car selected for the use of the Prince and Princess of Wales during their visit to Ceylon, is the 24-h.p. Panhard-Levassor Touring Car of Mr. Charles Wertheimer, which is shown in our photograph.

EXCELLENT as the Clement car has always been found for touring purposes in this country, it has been felt by Mr. E. H. Lancaster, who handles this vehicle in Great Britain, that the building of the car in its entirety should be under the control of the Company. In the past this has been the position, with the exception of the engine, but now arrangements have been concluded whereby the Vinot Engine Company have been amalgamated with the manufacturers of the Clement car, and the combination will be known for the future as the Clement Motor Company, Ltd., the control of which will still be in the hands of Mr. E. H. Lancaster, as managing director. The Vinot engine will, therefore, be fitted to all the 1906 Clement cars. This important and interesting information was given at a very pleasant little social gathering on Monday of this week, at which Mr. E. H. Lancaster had brought together his agents throughout the country so that they might in friendly consultation discuss the various points which they each and severally thought might conduce still further to perfecting and adding to the success already achieved with this type of vehicle. As heretofore, Mr. Lancaster will continue to visit the works in France at Pres St. Gervais at least once a month, by which means he is able to watch the progress of the improvements as they are introduced, and make suggestions specially applicable for the British market. As an earnest of the increased business which is coming forward for next year, already 56 Clement cars have been booked up, we learn, and the whole of the agents assembled on Monday evening expressed themselves more than delighted with the prospects in their various districts.

PAPERS to be read at the Automobile Club are announced as follows:—November 30th, "Morals from Olympia," by Mr. Filson Young; December 7th, "Results of Experiments Made During the Year by the Dust Committee," by Mr. W. B. Cooper. This paper will be accompanied by animated photographs lent by Mr. Wellington, of the British Automobile Commercial Syndicate.

ON Wednesday of last week a remarkable transformation was witnessed in the underground

repair shop at the Holborn Viaduct premises of the Winton Motor Carriage Company, when this large room was unrecognisable through the striking change which had been effected by means of draperies, carpets and ornaments. The occasion was the visit to England of Mr. Alexander Winton, the founder of the firm, a number of friends and members of the Press being invited to welcome Mr. Winton to London. The two toasts were "The King," proposed by Mr. Winton, and "All and Sundry," by Mr. Duck, the indefatigable London manager.

Mr. Winton proved himself to be particularly modest in regard to his own affairs, although he was justly proud of the manner in which he had built up the huge business of the Winton Motor Company in America, from the very smallest of beginnings. He told his guests of how he originally hired a bench at a dollar a week in a small shop, and later joined in partnership with his brother-in-law, who was the possessor of a blacksmith's shop. First starting cycle making, they ultimately turned out about 6,000 machines per annum. When cars came forward he started cautiously by building one vehicle, which he ran for about a year. He was then enabled to build half a dozen others, and ultimately brought the factory up to its present remarkable position of supplying an output of six and seven machines a day, whilst the extensions which have just been made provide for

A Novel Motor Hansom.—One of the new Cabs which are being built by the Vauxhall Co. for the Metropolitan Motor Cab Co. Except for the steering-gear and control-levers, the chassis is the standard 14-h.p. three-cylinder model, which is usually supplied as a touring car. Passengers obtain an unobstructed view by the relegation of the driver to the rear, but whether the driver himself will appreciate his elevated position, now that a steering-wheel replaces the ribbons, remains to be seen.

about twelve cars a day to be completed in the coming year. One of the special features on the Winton car is the pneumatic governor, and Mr. Winton, in mentioning this item, which he has been able to bring to a commercial state of efficiency, said he "stumbled on the pneumatic governor" in the early days of his experiences.

Premiums for Careful Drivers.—A good driver, it is generally admitted, can obtain fair results out of a poor car, but in combination with a first-class car he should get results approaching perfection. *Per contra*, a bad and careless mechanic can speedily ruin the finest car ever constructed, and no skill on the part of the manufacturers can counteract the effect of neglect or ignorance on the part of the man responsible for the driving of the car. Messrs. Chas. Jarrott and Letts are desirous of bringing this home to owners and drivers alike in connection with the De Dietrich cars, which they market in this country, and have determined to make the following special offer as an inducement to paid drivers to exercise the maximum of care in regard to this particular make of car. The offer is a payment of £100 under the following conditions:—

£50 to be presented to the paid driver looking after, or responsible for, the up-keep of any De Dietrich car either of the 1902, 1903, 1904, or 1905 types; and

£50 will be presented to the paid driver looking after, or responsible for, any De Dietrich car of the 1906 type.

The following are the accompanying conditions:—

An accurate detailed record must be kept for six consecutive months of all repairs and renewals to the car, excluding petrol and lubricating oil, which is not taken into account. A record must also be kept of the actual distance traversed during the six months.

These records must be signed by the owner of the car before being sent in, and in the case of the winner be verified by a statutory declaration made both by the paid driver and the owner.

The two drivers sending in the best records, *i.e.*, the records showing the smallest expenditure in up-keep per running mile, will secure the cheques for £50 each. The records must not date before the 1st of January, 1906, and any consecutive six months' record made between that date and the 1st of November, 1906, is eligible, but every record must be sent in not later than the 2nd of November, 1906. It is specially pointed out that only petrol and lubricating oil is excepted, that expenditure in tyres counts against the driver, and that the distance travelled is taken into consideration in his favour.

Owners of De Dietrich cars, it is hoped by this scheme, may appreciate these efforts to induce drivers to study their employer's interests, and induce them to keep a record, so as to qualify for the competition.

All records must set out dates, distances travelled and places, date and cost of each renewal or repair.

SOME country districts are recognising the importance of the motor wagon, and on Lord Scarborough's estate the tenants are reported to be organising a co-operative motor wagon service for running to market centres.

COMMERCIAL POINTS.

THE large number of visitors in town this week end for the Olympia Show was most marked, and many small motor parties were made to take advantage of the fine weather of Sunday. A very successful run was carried out by the Humber Company for some of their agents who were compelled to spend the week end in London. Leaving the First Avenue Hotel at a quarter past nine, Mr. T. C. Pullinger, the Beeston Works manager of the company, piloted a string of cars to the Brighton Road, and London-by-the-Sea was made in excellent time. After lunch at the Royal York, the return journey began at four o'clock, and the whole of the cars arrived back at the First Avenue Hotel together in procession, not the slightest hitch having arisen on either journey.

Amongst those who accepted the Humber invitation were Messrs. C. Ace, of Tenby; R. M. Wright, of Lincoln; J. V. Madgwick, of Bolton; I. S. Willway, of Bristol; H. J. Croft, of Kendal; R. Julian, of Reading; T. Garner, of Derby; J. Webb, of Monmouth; J. Fryer, of Kingston; A. Bell, of Manchester; K. Henderson, and I. Robinson. All these gentlemen are thoroughly experienced and expert, and expressed themselves highly delighted with the running of the Beeston Humber. One and all were highly delighted with their day's experience with the cars with which they are concerned.

A LARGE number of automobilists from the provinces will, of course, be in London during the present week, and Messrs. Argylls, London, Limited, of 17, Newman Street, Oxford Street, who are the London agents for the well known Argyll cars, point out that any automobilist visiting London who fails to pay their showrooms a visit will be neglecting an opportunity of seeing the most up-to-date arrangements which have yet been provided for the benefit of the motoring public. One of the great advantages which the Argyll Company provide for their customers is that any purchaser can obtain a car direct from stock, and practically take it away with him, an advantage which those who have had to suffer from two and three months' delay in delivery will fully appreciate. A feature of the Argyll showrooms is that in addition to the provision of automobiles, special stalls are provided at which up-to-date motor clothing can be purchased across the counter.

THE Continental Tyre and Rubber Company have brought out a small memento of the Tourist Trophy in the Isle of Man, at which the tyres of the Company so markedly distinguished themselves. It consists of a pamphlet showing a number of views of the course and a number of the cars which were shod with Continental tyres, a notable illustration being one of the Continental Tyre depots on the course.

There is no ending to the varied purposes to which the motor vehicle is now being brought into use. The above is one of the latest examples in the form of a 3-ton Orion garbage wagon, which has been built to the order of the Cairo Sewage Transport Company, Limited. It has a 20-h.p. engine, has steel wheels and rubber tyres, and all the parts are well covered in to protect them from the dust of Egypt.

Motor Boat Insurance.—An entirely new departure has been made by the Car and General Insurance Corporation for insuring motor vessels driven by fuel vapour. Although such business strictly comes under the heading of Marine Insurance, they have not the intention of undertaking marine business as generally understood.

The motoring public have, however, been giving, during the past two years, serious attention to motor boats, with the result that the construction of such vessels has become an important division of petrol motor industry. It has, therefore, been deemed an opportune moment to issue a special insurance proposal form for covering this class of risk, and a very full prospectus is to hand setting out the many advantages which the company offer to motor boat owners at moderate premiums. That the company, under the general management of Mr. F. Thoresby, are competent to deal with this side of the business, is self-evident from the fact that the chairman, Mr. E. Manville, and one of the directors, Mr. J. M. Gorham, are keenly interested, as directors of the Daimler Motor Car Company, in the construction of motor boats. Another director, Mr. R. Ward, is a director of the London and Provincial Marine Insurance Company. The company's solicitor, Mr. P. Marr Johnson (of Messrs. Clutton and Johnson), is a director of Saunders, of Cowes, one of the leading yacht builders in the world, and finally, the board will have the practical assistance of Messrs. Linton Hope and Co., A.I.N.A., as consulting naval architects, Mr. Linton Hope being one of the pioneers in designing petrol motor vessels, and the secretary of the Marine Motor Association, the governing body of such craft.

A Humber Excursion.—As showing the intense interest taken in the Stanley and Olympia Shows by all classes of the trade, it is worth noting that at seven o'clock last Saturday morning a special excursion left Coventry carrying over a thousand employees and friends of Messrs. Humber, Limited. The Humber Company closed its works for the day to allow its workpeople to come up to the Shows. The two huge exhibits of the company, at stands 130 and 18 (Minor Hall), at the Agricultural Hall were the centre of keen interest to the workpeople who have assisted in the manufacture of the cycles and cars exhibited there.

Mr. E. H. LANCASTER informs us that his Mr. Mosses has returned from a business tour through the counties, covering 2,000 miles. Mr. Lancaster states that the 1906 Clement Model used so impressed his agents that large contracts for next year's cars are already to hand. Early deliveries for next year are exceedingly good.

MESSRS. C. S. ROLLS AND CO. advise us that owing to the success of their Rolls-Royce cars, the factory is to be considerably extended, and they have resolved to confine themselves entirely for the future to the sale and manufacture of this now successfully launched British product. In regard to the Minerva cars with which the firm were dealing, they have made arrangements with Minerva Motors, Limited, for the orders already received for the 1906 Minerva cars to be supplied direct by Minerva Motors, Limited.

MESSRS. GAUTHIER AND CO., owing to the large increase in their business, have moved into considerably larger premises, their address for the future being 60, Great Marlborough Street (Poland Street Corner), Regent Street, W. The firm will continue as before, to be the sole representatives of the following French firms:—Malicet and Blin, chassis and component parts; Bassée and Michel, magnetos, coils, ignition apparatus; Ballot Frères, 2 to 4-cylinder engines; Louis Dubrulle, lubricators; Ossant Frères, silencers for automobiles and motor boats; Usine Partinium, metallic castings.

COMPANY DOINGS.

A. Darracq and Co., Limited.—Mr. J. S. Smith-Winby, the chairman of the company, presided over the third annual meeting of this company last week, when he had a very agreeable task in submitting the splendid result of the past financial year's working to the shareholders. He was able to state that the company had made a record advance in the amount of its business for the season of 1905, a record which it must be their endeavour to surpass in the year to come. The principal reason for this great success was the progressive policy of those in charge of the company's affairs, and the determination to continue to increase the capacity of the output of the works. The justification of this policy was found in the

figures which were submitted in the accounts. In spite of the competition, which had increased during the last two years, the Darracq Company's position was unquestionably stronger to-day than at any previous period of their business. In regard to consolidating their position generally, they had acquired the freehold of a portion of their factory at Suresnes and also extensive land adjoining. In addition extensive premises at Lambeth had been purchased, where they intended having facilities for examining, adjusting, and stocking a large number of cars in readiness for immediate delivery. They were also establishing there an effective repairing shop and giving other facilities which would conduce to the efficiency of the whole business. Although they had made such splendid profits, the additions to the works and plant at Suresnes would not really make themselves felt until the season, which was now coming on, so that they might look forward to a further increase of output in 1906.

In speaking of the splendid victories which had been achieved by the Company's racing cars, winding up the brilliant season by the winning of the Vanderbilt Cup Race in America, Mr. Smith-Winby paid a very high compliment to the Dunlop tyres. He said that almost at the last moment it was decided to use Dunlops, and they had fully justified their confidence. He took that opportunity of complimenting the Dunlop Company upon their enterprise upon this occasion. Within twenty-four hours of receiving the order they had despatched a full supply of tyres and trained assistance to New York, and the Company felt that no small share of the success that their car achieved in this spirited and severe encounter was due to the Dunlop Company's co-operation.

Dealing with the types of Darracq cars for next season, the chairman said that there would be two new models, one a 2-cylinder 10-h.p. and the other a 20-32-h.p. The latter he described as an enlarged and improved 15-h.p. car, the type which had had such remarkable success during the past year. They proposed to offer this new car at a very slightly higher price than the popular 15-h.p. and they hoped that it would not only equal but would eclipse the 15-h.p. in popularity. They hoped to get back the extra cost of this car by means of their increased output. The whole question of automobile manufacture was one of output. By the exceptional facilities which they possessed, they could offer advantages which smaller manufacturers could not possibly attempt, and it was becoming evident every day that the business was one only suitable for large concerns who could handle big quantities, those attempting to manufacture on a moderate scale being hopelessly handicapped from the outset.

He mentioned that for some months past they had had several specially-designed experimental delivery vans undergoing trials of the severest character. They were carefully studying the whole question of commercial vehicles, and later the company would be in a position to manufacture Darracq motors for light delivery van and commercial use, which would be profitable investments, he hoped, for the company and certainly for the buyers.

Referring to the net profit of £152,663, he dealt with the proposals which the directors recommended for dealing with this, including making up the dividend on the ordinary shares to 20 per cent. for the year, transferring £10,000 to reserve and carrying forward a balance of £27,174. He then referred to the proposals for the reconstitution of the company, which would materially increase the prosperity of the whole concern, and, in conclusion, Mr. Smith Winby asked the shareholders to voice their cordial appreciation of the efforts of those to whom the main credit was due for the results that were then laid before them. Included in this great appreciation was, firstly, their managing director, Mr. Darracq, and his staff at Suresnes, and Mr. Rawlinson, who directed the London office, ably assisted by Mr. Dunn and Mr. Cooke.

Sir W. B. Avery, Bart., who followed, and seconded the adoption of the accounts, said that the one name that the chairman had omitted to mention as having had a great deal to do with the success of their business was his own, and he felt sure that the whole of the shareholders would agree that they could not have a better chairman.

Mr. A. Darracq, who spoke in French, also attributed very largely the flourishing position of the company to the work of the entire board, notably of Mr. Smith Winby, their devoted chairman, and to Mr. Rawlinson, whose initiative and brilliant capabilities, sportive as well as commercial, were worthy of the very highest praise.

The accounts were unanimously adopted, and at an extraordinary general meeting subsequently held the proposals of the directors for the reconstitution of the company were also cordially approved.

THE directors of the London Motor Omnibus Company, Limited, announce an interim dividend at the rate of 10 per cent. per annum on the issued ordinary shares of the company for the six months ending 31st of October last.

NEW COMPANIES REGISTERED.

Arrow Motor Omnibus Company (Limited).—Capital, £100 in £1 shares.

Clement Motor Company (Limited).—Capital, £30,000 in £1 shares. Object, to acquire the business carried on at 3, Leicester Street, W.C.

Durham and District Motor Omnibus Company (Limited).—Capital, £3,000 in £1 shares. First directors, J. T. E. Dickeson, R. McLean, T. Colpitts, jun., J. Craig, J. Rowe, E. Short and W. Dornan.

A. Darracq and Co. (1905) (Limited), 2, Coleman Street, E.C.—Capital, £650,000 in £1 shares (375,000 preferred ordinary and 275,000 ordinary). Object, to acquire the business carried on by A. Darracq and Co., Limited, at Suresnes, France. First directors, J. S. Smith-Winby, Sir William B. Avery, Bart., E. Festus Kelly, J. Malesset, W. Weir, A. Darracq, and A. Rawlinson, being the present directors of A. Darracq and Co., Limited.

Evans Carburettor and Motor Pump Syndicate (Limited).—Capital, £2,000 in £5 shares. Object, to acquire patents for (1) new and improved carburettors and vaporisers; (2) motor pumps; (3) a compound nozzle for blowing compressed air, with a suction principle in combination therewith; (4) a radiator under an agreement with W. C. B. Evans and W. S. Cottrell.

Sharpe's Universal Patents (Limited), 178, Goswell Road, London.—Capital, £1,000 in £1 shares. Object, to take a business of motor engineers. First directors, N. W. H. Sharp and J. Stoddart.

Thames Motor Lighterage and Towage Company (Limited), 6, Crosby Square, E.C.—Capital, £10,000 in £1

shares. Object, to acquire and equip barges, lighters, and other vessels propelled by motive power for the carriage and transhipment of goods on the Thames and Medway.

Toboggan Motors (Limited), Terminus Chambers, Holborn Viaduct, E.C.—Capital, £5,000 in £1 shares. Objects, to acquire the rights in a three-wheeled petrol motor car known as the Toboggan Tri-Car; also a licence to use Tangy's Patent Friction Gear. First directors, H. E. Harrison, R. G. Batchelor, A. C. G. Smith and J. A. Leon.

Vanguard Motor Omnibus Company (Limited).—Capital, £100 in £1 shares.

NEW ISSUES.

A. Darracq and Company (1905) (Limited).—This company has taken over the business of A. Darracq and Company, Limited, of Suresnes, Paris. The share capital is £375,000 in 7 per cent. preferred ordinary shares and £275,000 ordinary shares, both of £1 each, and, in addition, £150,000 in debenture bonds are created, the whole debenture issue being offered at par. The directors are Sir W. B. Avery, Bart., Messrs. J. S. Smith-Winby (chairman), E. F. Kelly, J. Malesset, W. Weir, A. Darracq and A. Rawlinson.

London and South Coast Motor Service Company (Limited).—The prospectus of this company has been issued this week, with a capital of £100,000. The purpose of this company is for the running of public motor vehicles between London and the South Coast, serving en route districts such as Croydon, Woolwich, Redhill, Sevenoaks, Maidstone, Rochester, Canterbury, &c. The directors are Messrs. W. H. Davis, J.P., Thomas Prior, Carleton Roberts, J. W. Palmer and J. W. Cann.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

20179. 19th September, 1904. Improvements in Explosion Engines and Jacketing Arrangements therefor. Gustavus Green, 49, Reginald Road, Bexhill-on-Sea, and Joseph Miller, 1, Cantelupe Road, Bexhill-on-Sea. This invention has for its object a construction of the cylinders and valve boxes with their jackets, designed to simplify the manufacture, to increase the efficiency, and where required to reduce the weight of such jacketing devices. There are five figures. Fig. 2 shows the cylinder in section. Each cylinder, *a*, is cast with a projecting head, *b* and *a* flange or foot, *c*. The cylinders also have lugs, *d*, projecting therefrom for the connection of the valve box and collars, *e*, for holding the packing ring between the cylinder and jacket; *f* is the water jacket which may be made from piping or from sheet metal bent to cylindrical

and is made slippery by oil; the jacket, *f*, is then forced downward from above until its head, *g*, rests upon the flat top of the projection, *b*, on the cylinder head, its lower end passing over the packing ring, *m*. The jacket is locked in place by the screwing down of nut, *l*, upon the stem of plug, *h*. The hollow steam of said plug now forms through the passages, *k*, either an inlet or outlet for the cooling water to or from the water jacketed space. The rubber ring, *m*, is under compression against the inner walls of the jacket, *f*, and it not only allows of longitudinal differential expansion between the cylinder and jacket, but also prevents leakage when the cylinder and jacket expand circumferentially. For connecting the separate valve box a plate, *n*, is provided, having a hole therein corresponding to each of the holes in the lugs, *d*, on the cylinders. The jackets,

Internal Combustion Engines. John W. Eisenhuth, 25, Broad Street, New York, U.S.A. This invention relates to internal combustion engines working with gas, vapourised oil or spirit, and has for its object a new engine of the type wherein the gases work on the compounding principle, and four high pressure cylinders discharge into one double-acting or two single acting low pressure cylinders; the improvements consist mainly in the new construction or design of such engines, with the object of producing particularly compact and well-balanced engines. There are thirteen figures. Fig. 1, is a plan view, partly in section of this engine, having four high pressure cylinders and one double-acting low pressure cylinder. The four high pressure cylinders, *a*, *b*, *c*, *d*, and one double-acting low pressure cylinder, *e*, are all mounted in the one framing. The high pressure cylinders have trunk pistons, and the connecting-rods of the trunk pistons of cylinders, *a*, *b*, work upon a single crank on the crank-shaft, *g*. The pistons of cylinders, *c*, *d*, similarly work on a single crank standing at 180 degrees to the first. One of the rods has a forked end in each case, whilst the end of the other rod, *h*, work in the fork. Four rotary valves are provided of similar construction, but those on one side of the engine are preferably inverted as compared with those on the other side. There are two inlets, *n*, leading to carburettors or other sources of supply of combustible mixture. Each valve has a casing, wherein are mounted to turn two rotary sleeve valves. The casing and valves are tapered slightly so that they may be ground in, and the two valves are fixed on a sleeve through which the valve spindle, *s*, passes. The valves may be fixed directly on the spindle. The spindle, *s*, in this case, engages by a feather in the sleeve, and the sleeve is supported at its upper and lower ends in ball-bearings, *t*. By properly adjusting the valves, *p* and *q*, on the sleeve, and setting the bearings, *t*, the two sleeve valves, *p* and *q*, may be made to run over the faces in the valve casing just out of contact with these faces, true facing being ensured by the grinding in. In this way the frictional resistance, which has been the usual objection to the use of rotary valves may be avoided. *u*, is a single port or passage, constantly communicating with the interior of the valve casing from one of the high pressure cylinders. The lower valve part has a slot, adapted to register with a port leading from the inlet, *n*. The upper valve part, *p*, has a division plate or diaphragm, *y*, and two slots, the one below, and the other above the diaphragm respectively. The valves are actuated by the following means:—The crank-shaft, *g*, carries a toothed wheel, *6*, with which gear two idle pinions *7*, driving toothed wheels, *8*, on shafts, *9*, running transversely of the engine frame at each side of the same in brackets. The gearing, *6*, *7*, *8*, is so proportioned that the shafts, *9*, run at half the speed of the crank-shaft. The valve spindles, *s*, are driven from the half speed shafts, *9*, by mitre gearing.—November 1st, 1905.

form and suitably brazed or connected. The metal preferably used is brass or copper. The lower end of the jacket is open; at the upper end it has a cap, *g*, which may be formed by spinning over the metal of the jacket or by attaching a flat cylinder with its hollow stem projecting upwards and its head pressing against a packing ring lodged in a recess in the cylinder head. Holes, *k*, are bored through the stem of the plug, and the projection, *b*, on the cylinder head in order to form passages for the circulation of water; *l* is a nut screwing upon the stem of the plug *h*, and adapted to hold the jacket upon the cylinder; *m* is the packing ring of rubber or the like which forms the free joint between the jacket and the cylinder. In fitting the jacket the packing ring, *m*, is inserted between the collars, *c*,

f, are cut through over each of these lugs, thus leaving passages or ports in free communication with the interior of the cylinders; *o* are screwed plugs, the heads of which lie in recesses in the plate, *n*, the plugs being threaded to engage in internal threads in the lugs, *d*, of the cylinders; *p* are collars preferably of gun-metal shaped to fit between the outer walls of the jackets and the back of the plate, *n*. When the plugs, *o*, are screwed up, the plate, *n*, collars, *p*, jackets, *f*, and cylinders, *a*, are bound tightly together ready for the mounting of the valve box upon the plate, *n*. The jackets, *f*, are pressed to closely against the surfaces of the lugs, *d*, that no leakage is to be feared at this point.—November 1st, 1905.

PASSING EVENTS.

A British Triumph.

WHEN referring to the previous Automobile Exhibition at Olympia early this year we made use of the word "phenomenal," applying it both to the number of visitors and the large number of orders booked by the exhibitors. We are sorry we made use of that word, for it is one to which it is difficult to devise a comparative. We are accordingly left without a suitable adjective to describe the enormous advance which the Show (which closed its doors last Saturday) has demonstrated as having taken place since last February, both in the British automobile industry and the readiness of the British public to purchase automobiles. Last February the orders booked at the Exhibition represented a large sum. The value of the orders booked for the coming year is estimated by responsible authorities as being fully four millions sterling, and we have reason to believe that the bulk of these orders have gone to British manufacturers. The leading foreign firms have done very well, but British firms have done even better, and the amount of business transacted (for which, as said, an adjective fails us) is such as to fully justify the prophecies uttered in French papers by M. Georges Prade some six months and more ago, as to what the British automobile industry, and the British market for automobiles, would shortly become. There are no more acute buyers than the British purchasing public, and they have never hesitated

to go abroad, if necessary, for what they wanted. That the vast majority of them now are content to purchase at home, as the Exhibition demonstrates that they do, is the most irrefutable proof, if any were needed, of the statement triumphantly made by Mr. Edge and others, that Great Britain has not merely overcome the disabilities and deficiencies due to mistaken and reactionary legislation in the past, but at the present moment is well on her way to actually lead the world in automobilism.

The Attitude of Society.

THE Olympia Exhibition has further brought to light a marked alteration in the attitude of the public at large to the automobile. Certain classes, highly placed socially as a rule, have for long been the protagonists, and as Lord Montagu very properly termed them, the pioneers, in motoring. But what the orders booked and the experience gained at this year's Show prove emphatically is that what was till recently a fashion more or less confined to a relatively small class of society, now appeals to the bulk of the population who have money to become purchasers. It is a tremendous revolution for the automobile to have effected, and the result will be an almost incalculable development in the automobile industry. Considering that at the same time the majority of purchasers are purchasing British-built cars, the subject is one for all round congratulation.

When congratulating themselves, British manufacturers should have the kindest of feelings towards the fair sex. No one could have visited this last Show without being impressed by the enormous effect which the influence of interested ladies exercised in the placing of orders. In fact, but for their influence we feel certain that the colossal number of orders booked this year would have been considerably less enormous than it is. There was evidently an appropriateness in the old legend which almost invariably represented Venus as travelling through the air *in her car*!

A Seasonable Moment.

THE splendid object lesson which the Exhibition has provided of the swiftly growing importance of the British automobile industry is of particular value at the present moment. The sittings of the Royal Commission on the Motor Car Acts are in full swing, and the members have been hearing day by day the views and opinions of representatives of the movement and their opponents. When the sittings are over, the Commission will have to consider in its report what legislative proposals they will make as regards the future. We think they cannot but be advantageously impressed by the figures with which the Exhibition has furnished them. The British automobile movement has been shown by it to have advanced from a very backward position, as compared with other countries, to practically the foremost place, and its importance to everybody concerned, particularly to the British workman, is, as we have pointed out above, enormous. Oppressive measures and illiberal legislation were comprehensible—short-sighted and foolish as they were—in the days when it was doubtful as to what the future of the industry would be. Now that it is clearly shown that it has already become one of the most important staple industries of the country and will vastly increase in importance as time goes on—no industry, in fact, of modern times can point to such a rapid growth—the introduction of legislation which would seriously cripple it would be nothing less

than a national misfortune—particularly a misfortune to the working classes—and could be only regarded by unprejudiced critics as an attempt at national commercial suicide.

A Useful Field for the Heavy Lorry.

IN up-country mining districts, workings, which more or less belong to what might be termed the pioneer class of mine, not unfrequently find their chief difficulty to be the question of transport. Engineers, familiar only with European mines in which rail or canals often come up to the very shafts from which the minerals are raised, are likely to forget the enormous extent to which outlying mining industries are dependent for success on means of transport. The thanks of motor car manufacturers therefore, particularly those who make a speciality of building heavy luries for rough work, are due to the *Mining Journal* for the manner in which it has recently been drawing attention to the large number of mines in South America, Mexico, South Africa, India and many British colonies, in which horse and mule transport is at present alone relied on. Their rentability and chances of permanently paying a profit would be converted from their present decidedly perilous condition to a certainty, which would be extremely satisfactory to their shareholders, by the introduction of motor transport. Of course, for all mines that cannot actually load up into railway trucks or barges, the motor lorry, whether steam or petrol driven, should prove an enormous economy, though, of course, to a large extent in out-of-the-way districts the practicality of their introduction would depend upon the general condition of the roads, and these are often far from ideal. There are plenty of cases, too, in which, where mines under the same management are widely separated from one another, ordinary light touring cars are invaluable for enabling managers and engineers to keep adequate control of the works under them, and even the motor bicycle has been found to do excellent service in this respect.

Initiative Should Come from the Purchaser.

THE position of the heavy vehicle industry at present is such that there is, perhaps, no very great inducement for manufacturers, full up as they are with orders, to turn to fresh fields and pastures in mining districts for a market, so that the initiative must rather come from mine owners and managers. This initiative, we hope, thanks to the *Mining Journal*, to see more or less widely taken in the near future, and competent manufacturers approached with a view to the development of a lorry specially designed for mining purposes, in which the smallness of first cost must be far from the principal consideration. Absolute reliability and durability are, of course, the indispensable requisites of machines that may have to perform their duties in districts where repairing facilities may often prove to be far from ideal.

Needed for Mines at Home also.

EVEN within the British Islands, however, there is plenty of scope for the motor lorry in mining work, and this would appear to be particularly the case in Cornwall, where there are many important mines, situated at some distance from the railways, which are even still depending on horse traction. Even where not so dependent, and situated conveniently to railways, a curious circumstance comes in. The railway companies charge out of all proportion for small consignments of minerals below an amount of 5 tons, which is the usual load of a

truck. So much so is this the case, indeed, that many consigners find it comes cheaper to charter a whole truck and pay on 5 tons, even where they are only sending 2 or 3. At first sight this may not appear to be a serious matter, but with valuable ores like tin, where it is often necessary to get small consignments to their destinations at frequent intervals, the matter is a very serious one. In fact, the situation is such that there are good grounds for believing that a pick-up motor lorry service, which would take small consignments of ores from outlying Cornish mines, would prove not only profitable to its promoters, but a valuable boon to many small mineowners.

Fact and Fiction—A Triumph of Imaginative Journalism.—

THE FICTION
(See daily paper).

When going through the village of Charlwood a wagonette, driven by Mr. Coombe, of Reigate, was run into by a motor car, with the result that the car overturned the wagonette, and two ladies in the latter were thrown over a hedge and sustained serious injuries.

Mr. Coombe made every effort to gain the name and address of the chauffeur, but he did not stop, and raced away in the darkness.

This is the sixth accident of a similar character which has happened within a radius of five miles of Reigate within the last three weeks.

THE FACTS,

as stated by the driver of the car, were as follows:—

"A wagonette driven not by Mr. Coombe but by one of the two ladies, passed the car I was driving while the car was stationary, without the engines running, outside a house in which I was at the time. Shortly after passing the car, the wagonette was driven into a farm cart owned by the gentleman for whom I drive. The motor was nowhere near when this happened.

"Furthermore, as the car was back in the garage at 4.45, or, as near as I can estimate, fifteen to twenty minutes after the accident happened, the remarks about the chauffeur racing away in the darkness are absurd, as it was not lighting-up time.

"My employer will communicate with Mr. Coombe on the subject, and I am placing the facts before the secretary of the Motor Union."

We have had many efforts of imaginative attribution to motor cars of offences for which they were in no way responsible. But as a complete triumph of imaginative mis-description we think the above effort takes the palm. There is real genius about the statement that "this is the sixth accident of a similar character" on the Reigate Road. We wonder if the others were similarly reported and if they were equally true.

Marks of the Flowing Tide.

AMPLE proof of the substantial progress which the automobile industry has made in the last year, and of the pre-eminent position which it now occupies as a national industry has been provided by the Olympia Exhibition. Almost equally convincing evidence has been provided by the recent dinners of the two great automobile institutions of the country, the Automobile Club and the Motor Union. At both were assembled not merely representatives of the highest nobility and aristocracy, ambassadors from foreign powers, like Mr. Whitelaw Reid, and great servants of the State like Lord Roberts, but a perfect galaxy of all the talents were present as well. As our readers will see from our reports of both events, the speakers were most of them eloquent, often amusing, and naturally enough universally optimistic. But, perhaps, the most noticeable and effective speech, well-spiced with racy anecdote and

epigram, was that delivered by the famous patent barrister and expert, Mr. Fletcher Moulton, whose sense of humour has often made the gloomy precincts of the Chancery Courts peal with laughter during the hearing of the driest of patent lawsuits. It is of the highest importance to learn that Mr. Fletcher Moulton is now not only an automobilist but one who has become sufficiently enthusiastic to make so important a speech on its behalf. It is important not merely because his great intellectual gifts are now shown to be actively arrayed on the side of the motor car, but that as he is practically certain to hold office in the next Liberal Government we now know that we may look forward to having a powerful friend on the Treasury Bench should the ship of the State change pilots in the near future.

⊗ ⊗ ⊗ ⊗

"Motor Infantry."—When the Boer War was in progress, and for some time after it had come to a conclusion, the general public, and quite a respectable number of military authorities were convinced that the armies of the future would consist almost entirely of mounted infantry. They have all changed their opinions once again since the Russo-Japanese War, for circumstances alter cases so tremendously. When, therefore, authorities state that a revolution is likely to become general they must be understood as making the proviso "under certain conditions." This being understood, considerable interest attaches to the proposal made by Captain Paynter, of the Motor Volunteer Corps, in a recent lecture given at the Royal United Service Institution, that motor infantry, that is to say small bodies of infantry transported from point to point by automobiles, should form a regular arm of the service in future. The value of heavy automobiles for transport purposes we are all acquainted with, and the subject has been dealt with in some detail in our columns in connection with the Aldershot experiments. The use of the automobile for staff work, for conveying dispatches, and for enabling commanders to keep in touch with outlying posts, has been demonstrated over and over again in manœuvres in this country, and was shown to have practical value in the Manchurian campaign. The proposal to employ "motor infantry," however, is novel, and has got much to recommend it. Motor cars capable of travelling at a high speed and carrying from six to a dozen combatants at a pinch, could be used most effectively as supports to scouts, and for advance post work generally. They would have considerably greater mobility (given adequate roads) than mounted infantry, and would in many cases be quite as effective. Of course, their effective use involves two pre-suppositions — that the army to which they belong is operated on European or similar roads, and that the roads are not in possession of the enemy, but often enough in actual campaigning these conditions occur, and then motor infantry might do admirable service, particularly if, as Capt. Paynter suggests, light guns of the machine gun type were used for their support. The gift of prophecy is to some extent required to enable one to see how far the proposed arm is likely to prove effective, but that a proposal for its adoption should be made by a serious military authority in this formal and semi-official way, is a testimonial to the extent to which the automobile has convinced military men of its reliability and general usefulness.

THE 1906 SIDDELEY CARS.

Fig. 1.—Mr. Lionel de Rothschild's 100-h.p. Siddeley Racer, fitted with three-seated Touring Body. A description of this powerful chassis was given by us at the time that it ran in the Eliminating Trials for the Gordon-Bennett Race this year.

A FORTNIGHT ago we were able to give some of the leading particulars concerning the new cars which are being built by the Wolseley Company, but, at that time, no photographs were available, and we therefore had to fall back upon line drawings. Since that time, those of our readers who were able to visit the great Show at Olympia will, doubtless, have seized that opportunity of inspecting the excellent new models that were then brought before the public notice for the first time. Those who were not there, however, or who were unable to make a close inspection, will probably welcome the further illustrations which we now reproduce.

Fig. 1 is a view of the 100-h.p. racer that was built to the order of Mr. Lionel de Rothschild for the Gordon-Bennett Race this year, but is now fitted with a light 3-seated body for touring. It is shown with the bonnet

removed, and the large 4 cylinder engine is, therefore, clearly visible. Like the more powerful new series of Siddeley cars—of 18, 25, 32 and 70-h.p.—it is of the chain-driven type, but naturally all these standard models are of far more substantial build in every respect, and afford considerably more room for luxurious touring or landaulette bodies.

Fig. 2 shows the larger live-axle chassis, as seen from above, this model having an engine of 15-h.p. It is, however, practically identical with the 12-h.p. chassis, the chief difference being that the four cylinders are smaller. Well demonstrated by this photograph is the absence of all complication, and the "cleanness" of design, while the exceptionally long, outside springs that support the frame above the back-axle at once attract attention; these springs have, it will be observed, shock-damping top leaves that tend to prevent the lower leaves

Fig. 2.—View of the live-axle, 15-h.p. Siddeley Chassis which is one of the new models now being built by the Wolseley Company.

from separating when the car is travelling over exceptionally rough roads.

This same view also renders visible the torque-rod, A, although the lower member is hidden by the upper

their axes by the control-lever above the steering-wheel. Vertical push-rods, B¹, act upon the levers, B, in the same way as on the 32-h.p. engine and all four fulcrum-pins are connected together by the bar, B². A

further engine-control is provided by an automatic governor which is connected by the rod, C, with the throttle-valve, and also with an accelerator-pedal. Ignition is from accumulators, with high-tension plugs.

Very different in many respects is the 32-h.p. and other high-powered engines, an excellent idea of which is given in Fig. 4. Separate cylinders, cast complete with their heads, are employed, though the arrangement of the valves is the same as that on the smaller engines. Low-tension magneto ignition is fitted in addition to the ordinary high-tension system, the igniters being on the opposite side of the cylinders to the valves. Very neatly arranged, moreover, are the mechanical parts needed for ignition, these being all mounted upon, or driven by, a central shaft that passes across the centre of the crank-chamber. The commutator, D, is on one end of this shaft, the magneto is coupled up direct to the other end, and the longitudinal shaft which operates

Fig. 3.—The 15-h.p. Siddeley Engine, fixed in place in its "live-axle" Chassis; view from the "off" side, showing the combined Carburettor and governor-controlled Throttle-valve.

member. In reality it forms a triangular stay, which ties the axle to the frame, but has a swinging link, A¹, with cushion-springs, interposed at its forward end. No radius-rods are employed. Springs are introduced into the flexible couplings at the ends of the propeller-shaft to prevent end-play or any rattling, and the weight of the car is entirely removed from the live-shafts inside the back-axle, since the road-wheels run on the outside surface of the projecting axle-tubes. Except for these hub-bearings, ball-bearings are fitted throughout the transmission.

The compact gear-box, which provides three forward speeds and has the foot-brake just behind it, has very short shafts with wide gear-wheels; its operating lever works in a twin-slotted quadrant. Through the dashboard, the steering-pillar passes so that the steering-gear lies beside the engine, as seen in Fig. 3, and on the dashboard is a special mechanical lubricator for feeding the engine. This new lubricator contains revolving rollers that pick the oil up from the bottom, and scrapers that drain it off the top roller and cause it to flow down the feed-pipes to the engine.

All four cylinders on the 15-h.p. engine are enclosed in one aluminium jacket but have separate water-jacketed heads fitted with the inlet-valves above the exhaust-valves. One enclosed cam-shaft operates all the eight valves, and a modified form of variable-lift device has been adopted for the inlets. In the new design, the pivoted rock-levers, B, are carried upon eccentric fulcrum-pins, which are partially rotated about

Fig. 4.—View, from the "near" side, of the new 32-h.p. Siddeley Engine, fixed in place in its chain-driven chassis. In this illustration, the Variable-lift Inlet-valves, and the half-compression device for raising the Exhaust-valves are visible.

the igniters is gear-driven from it. Another novel feature of the same engines is the half-compression device for raising the exhaust-valves during the first part of the compression-strokes for facilitating starting. This is operated by a handle in front of the radiator and by the connecting-bar, E. The gear-driven circulating pump, F, with its exceptionally long bearing, is also prominent in Fig. 4.

THE NAPIER PETROL LANDAULETTE.

(Concluded from page 1460.)

Fig. 4.—The Napier Landaulette. View of the Chassis from above, showing the underframe for the engine, and the position of the driving chains inside the frame.

The Frame and Transmission.

CONSTRUCTED of armoured wood, the main frame is absolutely rectangular when viewed from above, for, owing to the position of the engine and radiator, it has not been necessary to depart from the simplest accepted lines. In front, the frame is carried on the usual semi-elliptic side-springs, but at the rear a third spring has been introduced in order to afford easier riding. This latter is also semi-elliptic, but is inverted and placed transversely, so as to connect the ends of the side-springs and support them by its attachment to a bracket which is carried out from the main frame to meet it. This suspension is very clearly indicated in Figs. 4 and 6, the former showing the arrangement when viewed from above, and the latter when observed from behind. It will be noticed in these illustrations, too, that the two rear side-springs are placed beneath the frame instead of at the side, and that they are supported by the axle in rather a peculiar manner owing to the arrangement of the chain-drive. Instead of resting on the axle proper they are hung below the tubular axle ends carrying the short driving shafts, the axle itself, which is bent, passing across underneath them. In front, there is nothing unusual, except that the position of the steering-column brings the steering-gear—which is of the worm and sector type—in front of the axle, but the connections are not greatly modified on this account.

Immediately behind the engine is the clutch, which is enclosed in the fly-wheel and is of the leather-faced cone type. It is not peculiar in itself, but the inner member, which is fixed to its shaft, is operated from

the other side of the gear-box. Sliding the gear-shaft in this manner, in order to operate the clutch, has always been standard practice on the 18-h.p. Napier chassis since its prototype was first introduced in 1903, but it is not often employed on other cars at the present day. In many respects, this landaulette chassis is similar to that of a new Napier touring car which we described in July, 1903, and it gives an insight into the sound English principles of high-class construction which have always held sway in the Napier works, that a type which was introduced then should still be a popular model to-day, and it is little wonder, in the light of this, that a great deal was thought of the original cars when they were first brought out. At that time, too, the floating gear-box

Fig. 5.—The Napier Landaulette. View showing the arrangement of one of the side chains which are placed inside the frame in order to leave an unobstructed entrance to the carriage.

Fig. 6.—The Napier Landaulette. Rear view of the chassis, showing the suspension of the main frame and the construction of the rear-axle, with its hollow ends, which support the short chain-driven axles.

was a great feature, and, if we remember rightly, it was a novelty at that time. It is still employed, and the gear-box rides, as will be seen in Fig. 4, on the differential countershaft at the rear end, and is hung in front by

a single bolt passing through one of the transverse members of the frame. Four speeds and a reverse are available, and the speeds are introduced by moving a single sliding sleeve, on what is generally called the Panhard system.

Practically the only new feature in the transmission is the rearrangement of the side-chains in order to leave the frame unobstructed on the outside. They have, for this purpose, been ingeniously mounted on the inside, and they drive the road wheels through short live-axles which are supported on extremely long bearings. An illustration of this arrangement is given in Fig. 6, where the great length of the bearings supporting the driving axles, and the manner in which they form part of the bent stationary axle itself, is clearly visible. In Fig. 5, one of the brackets supporting the counter-

shaft is shown; normally, of course, the chain-sprocket would have been placed outside on the projecting end of the shaft, instead of in the position which it does occupy.

Royal Commission on Motor Cars.—Further witnesses heard by the Commission sitting under the chairmanship of Lord Selby are Mr. Thos. Munro, clerk to the County Council of Lanarkshire; and Mr. A. G. G. Asher, clerk to the County Council of Midlothian, on behalf of the Association of County Councils of Scotland; Sir John Macdonald (Lord Kingsburgh), Lord Justice Clerk of Scotland, President of the Scottish A.C.; Mr. R. J. Smith, Hon. General Secretary of the Scottish A.C.; Mr. A. Vernon and Mr. J. Willmott, representing the Surveyors' Institution; Mr. Robert Black, county surveyor of Inverness; Mr. James Perry, county surveyor of Galway; Mr. James Boyce, of Scarborough; Miss Evelyn Everett Green and Colonel Bardwell, M.F.H., on behalf of the Highways Protection League; Mr. A. Murray, representing the Convention of Royal Burghs, Scotland; Mr. C. R. Dykes and Mr. G. R. Jebb, on behalf of the Canal Association; Mr. T. H. B. Heslop, county surveyor of Norfolk; Mr. W. Tanner, county surveyor of Monmouth; Mr. G. Montagu Harris, secretary of the County Councils Association; Mr. C. M. Pilkington, Nottingham; Mr. E. Storm, Nottingham; Mr. F. Knight, Tamworth; Mr. G. P. Langridge, and Mr. C. H. Todd, on behalf of the Motor Union; Captain J. A. Cole, Lincolnshire Automobile Club; Captain the Hon. G. A. Anson, Chief Constable of Staffordshire; and Dr. Melville Thomson, Bath, on behalf of the Highways Protection League.

Local Option.—Really we should have a terrible state of affairs if the recommendations of local authori-

ties could become binding at once without the approval of the Local Government Board. An ordinary full-sized ledger would not be big enough to contain the information that every driver would require as to what he might do in one district, and what he would have to refrain from doing in one county or another. The Surrey County Council at its last quarterly conclave decided that in their opinion the maximum speed for motor cars on rural roads in the day-time should be 20 miles an hour, but only 15 between sunset and sunrise, while in towns and villages the maximum speed should be 10 miles an hour at any time. The Surrey County Council also desire to make the owner of the car, when present, responsible jointly with the driver for the speed at which the car is travelling, and further desire that the owner should be compelled to furnish the police with the name and address of the driver in all circumstances when required. They further think that the person for the time being registered as owner of a motor car should in all cases be responsible in the civil courts.

THE Company of Coach Makers and Coach Harness Makers again offer, amongst their competitions for British subjects, a prize in connection with motor car work. The offer is a first prize of a silver medal and ten guineas, and a bronze medal and five guineas, for drawings of a limousine motor car with fixed hood and extension front, to carry five people in the body and one by the side of the driver.

THE NEW ARROL-JOHNSTON PETROL CARS.—PART III.

(Continued from page 1469.)

THE water-jacket of this 12-15-h.p. engine is of ample size, and passes around the two parallel cylinders. Both cylinders are bored out right through the casting, the combustion-chambers being formed

occurring each second revolution in each cylinder—and since the two cylinders are arranged so that they fire alternately, it follows that the crank-shaft receives an impulse from both connecting-rods every time it comes round.

The effect produced is thus equivalent in some respects — mechanical balance and regularity of explosions—to that of an ordinary 4-cylinder engine, although, of course, there are not two impulses per revolution.

Communicating through a short port with each combustion-chamber are the separate, detachable valve-chambers, A³, these being bolted centrally to the sides of the cylinder-casting, A, as seen in Figs. 9 and 12. Each valve-chamber is provided with an exhaust-valve, A⁴, an atmospheric inlet-valve and a low-tension (make-and-break) igniter, the valve-rods lying vertical—as in most engines—and the inlet-valve being immediately above the exhaust-valve. The igniters are formed by two independently fitted parts—the non-insulated, moving contact-arm, and the insulated, stationary contact-plug, A⁷.

The inlet-valves, complete with their seats, are held down by the induction-pipes, A⁴, and by yokes fitted immediately above the valves. Either valve can, there-

Fig. 13.—The 24-30-h.p. Arrol-Johnston Engine, fixed in place in the Chassis. View from the "near" side showing the Valves, the Igniters, and the detachable Cam-shaft Casing, D⁹.

between the two pistons, A¹, in each. Passing through the crank-chamber, B, at right-angles to the cylinders, is the two-throw crank-shaft, B¹, the long bearing-brackets, B², for which are bolted to the main casting, B. The ends of the two castings, A and B, are machined off flush with one another, so that the detachable covers, C, fit up against both with a flat face-joint, but there are projections, B³, on the latter, to carry the trunnion-pins, B⁴, for the rocking-levers, C¹. It is these two rocking-levers, C¹, that couple up the four pistons, A¹, with the two connecting-rods, C², one of which passes into the crank-chamber from each side. It should, perhaps, be more fully explained that the two pistons on each side of the engine are both coupled up by independent links, A², to their own rocking-lever, C¹, and that one of the connecting-rods, C⁴, enables each rocking-lever to operate upon the crank-shaft.

From what has already been said, it will have been gathered that, whenever an explosion occurs in either cylinder, the two outwardly-forced pistons operate simultaneously upon the crank-shaft, and that a more or less perfect balance results from the fact that the force is equally applied in two opposite directions through equally heavy, and precisely similar, moving-parts. In other words, both connecting-rods are forced inwardly, one giving an impulse to one crank-pin, while the other acts upon the other crank-pin. The engine works, of course, on the ordinary four-stroke cycle—an explosion

Fig. 14.—The 24-30-h.p. Arrol-Johnston Engine. View from the "off" side, showing the Carburettor, D⁶, the Magneto, E², and the Circulating Pump, E⁵.

ore, be removed readily, since it is only necessary to release the yoke and swing the induction-pipe up out of the way. A kind of hinge is provided, for this purpose, by the large unions that connect the induction-pipes, A⁴, to the throttle-valve, A⁵.

Close up to the throttle-valve, A⁵, is the simple float-feed carburettor, A⁶, which has an inspection-cover above the spray-jet. That portion of the supply which passes

the spray-jet is drawn in direct from the atmosphere through the U-shaped tube seen in Fig. 8, but an auxiliary supply can also be admitted direct to the throttle-valve, A⁵, through the silencing chamber that is fixed immediately above it. The throttle-valve not only permits the richness and the volume of the explosive mixture to be varied, but it also enables the driver to admit pure air to cool the cylinders when the car is descending steep hills.

Each exhaust-valve, A⁶, is operated from its own half-time shaft, and the same cam-actuated mechanism that controls it also works the igniter in the same valve-chamber. Both the cams, B⁵, are visible in our illustrations, lying as they do close up to the crank-chamber-casting, B. The cam-shafts, B⁶, are quite short, merely passing through from the inside to the outside of the chamber in order to connect the large enclosed gear-wheels—which mesh with the half-sized pinions, B¹, on the crank-shaft, B¹,—with the exposed cams, B⁵. Not

chamber. From the pump, C⁴, the oil is led by the two pipes, C⁵, up into the hollow trunnion-pins, B¹, whence it is conducted through special passages, drilled in the various moving parts, to all the bearings and to the pistons. After performing its work, it finds its way back to the bottom of the crank-chamber, where it is again caught up by the pump.

A similar type of pump is also employed for the cooling water, but this is fixed—as seen in Fig. 9—in front of the engine. The larger spur-wheel by which it is driven from the crank-shaft, B¹, contains the centrifugal governor, and the smaller spur-wheel (on the crank-shaft) has a sprocket alongside it for driving the magneto by a chain.

This remarkable engine has so fully proved its reliability, durability and efficiency that nothing further need be said as to its merits in these respects, and the description which we have just given will have served to show that every part is much more simple and accessible than

Figs. 15 and 16.—Longitudinal and Transverse, Vertical Sections (partly in elevation), showing the construction of the 4-cylinder, vertical, 24-30-h.p. Arrol-Johnston Engine.

only does the external mechanism act direct upon the exhaust-valves, but it gives a very quick "break-action" to the igniters. Experience has shown that there is no need to fit any hand-controlled "timing" gear for advancing or retarding the ignition whilst the engine is running, but provision is made for adjusting the firing moment, from time to time, if necessary; apparently the action of the magneto and of the trip-mechanism has the effect of automatically compensating for variations of engine speed. For facilitating starting, relief valves are fitted to the valve-chambers, just beneath the igniters, these being manipulated by a lever in front of the car.

In Figs. 11 and 12, the oil-pump, C⁴, is seen in place in the base of the crank-chamber. It is of the spur-wheel type, and is gear-driven from one of the large half-time gear-wheels. The well, in which it is situated, is sufficiently deep to prevent the connecting-rods from splashing in it, and consequently the lubrication of the entire engine is not only automatic, but remains constant, irrespective of the precise quantity of oil in the crank-

is at first sight apparent. It only remains, therefore, to mention that it is thoroughly well made from the best materials that are procurable, and that it runs very steadily in the new cars which the Company are building. In the matter of flexibility, it is extremely satisfactory, enabling the car to be driven quite slowly, or to be started from rest on the top gear on comparatively level surfaces. The bore and stroke are $4\frac{1}{4}$ and $6\frac{1}{2}$ in.

The 24-30-h.p. Vertical Engine.

Although the 4-cylinder Arrol-Johnston engine is in the main similar to those with which most motorists are familiar, it yet has several novel features, some of which have been borrowed from the special 12-15-h.p. model. In Figs. 13 and 14 it is seen, from both sides, fixed in place in the standard 24-30-h.p. chassis, and in Figs. 15 and 16 are given sectional drawings that show the entire construction.

Each cylinder is formed by a separate symmetrical casting, fitted with studs at the top for holding down the

jacketed cylinder head. Around the cylinder proper is a thin copper jacket, which is corrugated to allow for expansion, and is clamped firmly between the cylinder and the head-casting. Through this joint, ports are cut to allow the water to pass from the lower jacket up into the upper jacket, but the copper itself constitutes a gasket-joint for the combustion-chamber.

Formed on one side of each cylinder-head is a valve-chamber which receives the inlet-valve, D^3 , above the usual type of exhaust-valve, and this valve-chamber is also fitted with a low-tension igniter of the same design as that employed for the smaller engine, as well as with an ordinary high-tension ignition-plug, E^5 . The cylinder-heads are cast with large passages, D^2 , leading across to the inlet-valves, D^3 , from the opposite side of the engine, and thus the induction-pipes, D^1 , are rendered quite simple fittings although the carburettor, D^6 , lies on the further side from the valves. Quite short, too, are the exhaust-ports, D^8 , that lead the gases into the common exhaust-pipe-fitting, D^7 .

Another interesting feature is that the cam-shaft, which operates the igniters and the valves, can be easily removed if necessary, since the upper portion, D^9 , of the casing containing it is made separately, and is bolted to the main crank-chamber-casting. This detachable portion also carries the gear-driven commutator, E^4 , which is used in conjunction with the auxiliary accumulator system when the high-tension plugs are employed. As our illustrations show, the inlet-valves D^3 , are actuated by the push-rods, D^4 , through the rocking-levers, D^5 , while the former also serve to operate the moving members, E^1 , of the low-tension igniters; the trip-motion

that gives a quick break at all times is connected with a rod, E^3 , in such a way that the time of ignition is retarded automatically when starting the engine.

Fixed to the main portion of the crank-chamber are the magneto, E^2 , and the water-pump, E^6 , both of which are driven by gear-wheels from the crank-shaft. From the pump, the water is led by the pipe, E^7 , to all four copper jackets, and from the top of the cylinder-heads it passes back to the radiator by the pipe, E^8 . All the gear-wheels at the front end of the engine are enclosed in the crank-chamber, but they are all readily accessible.

Our sectional drawings show the oil pump, F , in the base of the crank-chamber, and the manner in which it is driven from the crank-shaft. They also show the arrangement of the entire lubricating system. The base casting is quite independent of the crank-shaft bearings, and merely serves to catch and retain the oil ready for the pump to feed it through the pipe, F^2 , and the passage, F^4 , to the central bearing. From this bearing it is led by holes drilled in the crank-shaft to all the other bearings, and up to the hollow gudgeon-pins and the pistons by the pipes, F^5 , which are fitted alongside the connecting-rods. Every part is thus fed positively and automatically. In conjunction with the pump, there is a gauge, F^1 , on the one side to show the level of the oil, and a relief-valve, F^3 , on the other side, this valve returning any surplus oil direct to the well if the pressure increases abnormally. An oil-bath is formed around the cam-shaft, the oil being caught by it as it escapes from the pistons.

The cylinders of this 24-30-h.p. engine have a bore of $4\frac{1}{4}$ in., and the stroke is 5 in.

(To be continued.)

"Red Lion and Crown" Cars.—Some curiosity has been not unnaturally experienced with regard to the information which we recently published, that electrically propelled vehicles would be exempted from the ordinance excluding motor vehicles from the parks during certain hours in summer, as to how the police will distinguish them from the very similarly shaped petrol vehicles which we last week christened "mock electrics." The difficulty is, we understand, to be solved as follows:—The licensing authorities for vehicles in the metropolis are arranging to specially license electromobiles in future, and cars so licensed will be embellished with a large red lion and crown painted upon them. It will, of course, be an offence for anyone to put this distinguishing mark on any vehicle not electrically propelled, and one of the conditions of this special registration is to be that the owner of the car will be jointly responsible with his driver for offences against the law.

The Lebaudy Airship.—We have recently described the successful evolutions of the Lebaudy airship in the neighbourhood of Toul under the inspection of the Aeronautical Department of the French Army. Of course, the object of the demonstrators has hitherto been to show how successfully the airship could maintain itself at a regular height above the ground. Questions, however, have been raised as to whether the airship was capable of rising sufficiently to escape, if need be, projectiles launched against it by a possible enemy. The last demonstration was, therefore, directed to satisfying the military experts that the solution of this problem

involved no difficulties. The airship rose to a height of 200 metres, at which it was enveloped in thick mist, and gradually, by throwing out ballast, rose to a height of 800 metres. At this elevation the town of Toul could be perceived from time to time, the airship continuing to execute evolutions in absolute accordance with the desires of its pilot. Finally, it attained a height of 1,370 metres above the sea level, that is to say, 1,120 metres above the point from which it had started, having thrown out 320 kilogs. of ballast. Continuing its evolutions at about this height, falling and rising as required, it finally came to earth to the south-east of Toul. It was still provided with 150 kilogs. of ballast when it came to earth. This demonstration finished the series of experiments with the Lebaudy airship which the military authorities have been conducting, and the gas-vessel has now been deflated, and the staff of engineers and their assistants who have been concerned in these triumphant operations are returning to Moisson to carry on further experiments. From October 8th to November 10th the airship went out practically daily, and often carried six passengers. It made reconnaissances outside the entrenched camp of Toul and from there to Nancy. Experiments have been made with dropping projectiles, long-distance photography, and other subjects of interest, and the airship has been raised without any difficulty to a height at which it is generally admitted a balloon is absolutely invulnerable. This latter point is important, as there have been people—we will not say authorities—who have disputed the possibility of a navigable balloon accomplishing it.

THE 1906 WINTON CARS.

(Continued from page 1462.)

The 25-h.p. Winton Car.—View of the complete car, fitted with handsome side-entrance body.

AN unusual feature in the pressure feed system is the employment of a mechanical air pump instead of utilising the exhaust. This pump, D, is mounted directly above the larger pump, B, and its piston is carried on the same rod. In addition to feeding the petrol, however, it is also used for filling the lubricator on the dash, from which the oil is mechanically forced to the bearings.

High-tension battery ignition is now the only system used on these cars, and the gear-driven commutator for distributing the primary current is mounted in an accessible position near the engine. The high-tension ignition-plugs are mounted centrally in the cylinder heads, but the tops of these only are just visible in Fig. 2, as they are partly obscured behind the inlet-valve chambers. Each wire is independently supported close up to its plug by an insulated ring, E', formed solid with the water pipe which passes above the cylinders. Circulation is effected by a gear-driven centrifugal pump mounted on the side of the crank-chamber, where it is in the p
the p
struc
is a
fricti

eliminate any strains which might otherwise be set up through sudden acceleration or retardation of the engine.

With so many gear-driven attributes to the engine, the arrangement of the spur-wheels naturally presents features of interest, especially when it is remembered that they all have to be on one side of the engine in order to carry out the scheme for accessibility, which is exemplified in the vertical division of the crank-chamber. The main spur-wheel of the system is, therefore, mounted on the cam-shaft instead of the crank-shaft, and the others are set like planets around it. Neither the fan nor the commutator could conveniently be driven direct from this wheel on account of their relative positions, and the necessity (in the case of the latter) for a specific gear ratio. Idle wheels have, therefore, been introduced, and the commutator, requiring a double reduction, is driven through a second train of wheels, F', F', which are pro-

The 25-h.p. Winton Car.—Side view of the chassis showing the double springs.

THE NEW 12-15-H.P. DE DIETRICH CAR.

(Concluded from page 1464.)

Fig. 4.—The 12-15-h.p. De Dietrich Car.—View of the chassis from above.

The Frame and Transmission.

TUBULAR cross-members are employed to stiffen the side-members of the main-frame which, as usual, are pressed with a tapering section, and narrowed together at the dash in order to secure a wider steering lock with a moderate track. At the rear of the frame the ordinary channel section cross-member is employed, but in front another straight tubular distance piece is used instead of fixing a cross-member below the radiator. This is done in order to allow the engine to be drawn forward before removing it from the frame. Semi-elliptic springs support the frame at each end, and those at the rear lie outside, instead of beneath, as is now almost invariable practice. The front axle has straight ends which hold the forks on the hubs of the front wheels by vertical pins passing through them.

Behr
steeri
featu
is of a
issue

nut and rack, and has provision for taking up wear, while another special feature is that the construction affords support to the steering-lever on both sides, instead of allowing it to overhang, as it does in most systems.

Accommodated in the fly-wheel is the leather-faced cone-clutch, which is of special design. It is similar, however, to that employed on the larger cars, and the very full description which we gave on July 22nd, 1905, not only describes its peculiarities in detail, but also illustrates how easily it may be dismantled. Simplicity in this respect is one of the features of this car, but the arrangement of the clutch gear is one of the most pleasing of its numerous well-designed details in construction, for it is an excellent example of how simple, and yet how accessible, the ordinary cone-clutch

Fig. 5 —The 12 15 h.p. De Dietrich Car.—Side view of the chassis.

can be made. Adjustment is also easily accomplished because the clutch-spring is stationary, and, being placed against the frame, can be reached from the outside.

Between the clutch and the gear-box is a shaft which has a universal joint at both ends. The gear-box, itself, is supported on two of the tubular transverse members of the main frame, and the method of carrying it is clearly shown in Figs. 4 and 6. At the rear end, the box is fixed directly in place by sockets formed by the halves of the main casting, but in front it is suspended from

intended to enable the top half to be entirely removed without disturbing anything. Ball-bearings are employed for the gear-shafts, and the four speeds are introduced by means of a single sliding-sleeve, which is operated by a lever working over a "straight-through" quadrant. In order to render self-alignment possible, universal joints are introduced into each half of the differential-countershaft, this being one of the special features which was first introduced on that De Dietrich model which created such a sensation at the last Paris Salon.

Very powerful brakes are provided, that on the countershaft being of the hinged band type, and those on the rear wheels having internal expanding shoes. No special features have been introduced on the foot-brake, nor on the hub-brakes, so far as the brakes themselves are concerned; but one very ingenious fitting is provided in the side-brake mechanism, which should be a

Fig. 6.—The 12-15-h.p. De Dietrich Car. View of the Gear-box, Clutch, and Dash, also showing the Spring Buffer, B, in the side brake mechanism, and the Small Lever, A, on the dash, which shuts off the petrol supply at the jet.

two clips which support steel rods secured to the gear-box, so as to form brackets. This method of construction thus removes the necessity for casting long aluminium arms on the gear-box, merely in order to support it, and while thus making for strength and neatness it also facilitates the work of erection.

These steel rods are attached to the lower half of the box, whereas the weight is carried by the top half at the other end. An additional support, however, is provided at the rear end by attaching a hook to the lower half of the gear-box, but this is not normally in use being only

It is stated by the *Sussex Daily News* that the ravages wrought by motor cars on the main Brighton roads are so terrific, that the East Sussex Council has voted £1,000 for necessary repairs. Well, the Council is responsible for half of the road between London and Brighton, and, presumably, they

Fig. 7.—The 12-15-h.p. De Dietrich Car. Another view of the Gear-box, showing one of the universal joints in the differential countershaft.

distinct improvement—in fact, it is remarkable that the idea has not long ago become general practice. In the main brake-rod is a spring buffer, B, formed by a helical compression spring enclosed in a metal case. It takes up practically no room, and does not interfere in any way either with the adjustment or the use of the brakes, but it is calculated to improve their action by making it possible for them to be applied with a varying pressure. In an ordinary brake system the shoes are either hard on or quite clear, the only difference in pressure available being that due to lack of rigidity in the connections, but in the De Dietrich side-brakes a cushioning action is afforded by the device specially designed for the purpose.

Dimensions.

Wheels: 870 mm. by 90 mm. both back and front.

yearly vote a substantial sum for its up-keep. That motor cars are responsible for the damage is, of course, an absurdity, but no doubt we shall now find every District Council, when arranging for the repairs of its roads, explaining that the expenditure is due to the damage caused by automobiles!!!

THE NEW 14-22-h.p. GERMAIN CAR.

(Continued from page 1465.)

Fig. 2.—The 14-22-h.p. Germain Car. View of the Dash showing the pedals; that on the extreme left is for slowing down the engine, and it is adjacent to the clutch-pedal, so that both may be pressed simultaneously with one foot.

CHANNEL section cross-members are used to stiffen the frame, and these also support the gear-box, which is secured rigidly to them. Three speeds and a reverse are available, and on the top speed the engine is connected direct to the live-axle. Only one sliding member is used to provide the three changes of speed, and the lever works over a "straight-through" quadrant, which is ingeniously constructed so as to do away with the necessity for a trigger on the lever itself. The quadrant is mounted on small springs so that it moves bodily outwards when changing gear, and flies back into position directly the lever comes opposite to a notch. Between the gear-box and the back axle is a long exposed propeller-shaft which has a

Fig. 3.—The 14-22 Germain Car. View of the rear-axle, showing the horizontal division of the casing and the triangular torque-rod.

universal joint at each end. Short radius-rods tie the axle-casing to the frame and a long triangular torque-rod prevents it from unduly twisting, while at the same time giving a certain flexibility to the drive on account of the spring suspension at its forward end. Owing to a horizontal joint, the differential gear is rendered very accessible, and a very neat appearance is also given to the back axle as a whole by the casing being kept as small as possible. Instead of mounting the road-wheels on the axle itself they are carried on extensions of the axle-casing, which thus relieves the live-axle of anything but a purely torsional strain. Ball bearings are employed in the hubs of the road-wheels and also throughout the transmission. An ordinary leather-faced cone-clutch is fitted in the fly-wheel of the engine, but the clutch spring is stationary, and in such a position that it is easily adjustable. Very large internal expanding brakes are provided on the rear

Fig. 4.—The 14-22-h.p. Germain Car. View of the engine from the inlet-valve side, showing the Eisemann High-Tension Magneto and the variable lift mechanism below the push-rods of the valves.

Fig. 5.—The 14-22-h.p. Germain Car. View of the engine from the exhaust valve side, showing the gear-driven circulating pump. Brass jackets, secured in place by shrunk steel rings without brazing, are fitted to the steel cylinders.

wheels, and immediately behind the gear-box is a strong external brake of the locomotive type.

The Engine.

Particularly neat is the four-cylinder engine with its smooth brass water-jackets surrounding the separate steel cylinders. This form of construction has been a feature of Germain cars in the past, and a description of the construction appeared in our issue of February 4th, 1905. It will be remembered that each cylinder is bored from the solid bar and is turned with flanges at each end, the bottom flange serving for fixing it to the crank-chamber, and the top flange providing an attachment for its cast-iron head. One end of the brass jacket is kept water-tight by the joint between the head and the cylinder-flange, while the other end is secured by a steel ring which is shrunk over the jacket. This ring, it will be observed, has to be heated *in situ*, because it cannot be slipped on from either end once the jacket is in place. Water passages are provided through the two flanges at the top, consequently it has not been necessary to provide a separate water service to the heads as well as to the cylinders.

Unlike the larger Germain models, this engine has its valves arranged on opposite sides, and there are, therefore, two cam-shafts. Very neat variable lift devices are fitted to the inlet-valve push-rods, and the engine is controlled by them from a hand lever above the steering wheel. In the induction-pipe also, however, there is a

throttle-valve, but this is only connected to a foot pedal and normally remains full open. Its object is to enable the driver to slow down the engine whilst changing gear, by pressing both it and the adjacent clutch pedal simultaneously.

No special features have been embodied in the carburettor, which is of the simple float-feed type, having a supplementary air port capable of being reset by hand whenever it may be considered necessary to do so.

Symmetrically arranged on either side, are the Eisemann magneto and the circulating pump, both being gear driven from the cam-shafts on their respective sides. Timing of the ignition is provided for by means of a hand lever above the steering wheel, and the neatness of the ball and socket connections between the rods, used in performing this operation, is one of the many evidences of careful high-class construction, which are plainly visible throughout the chassis. In front of the engine, mounted on a bracket, secured to the crank-chamber, is a belt-driven fan, and the belt can be tightened when required by rotating the eccentric bush by which the fan spindle is carried in the bracket. Lubrication of the bearings is carried out on the drip-feed system, oil being forced up to a sight-feed fitting on the dash by exhaust pressure. In addition to the engine bearings, those in the gear-box and the differential are also lubricated from the same source.

“IS NOT THE MOTOR ‘BUS BUSINESS

UNDER the above heading *The Financial News* have, in Wednesday's issue, a critical article upon motor omnibus flotations. We have repeatedly published warnings against the laying hold of the automobile indiscriminately by company promoters, mainly for the purpose of securing funds from the public. The danger is a real and vital one to the motor industry, and should be stopped at any price. We are glad, therefore, to see our financial contemporary expressing the same views upon the subject which we have so frequently enunciated.

The following extract is the conclusion of the article to

BEING JUST A TRIFLE OVERDONE?”

which we refer:—

“There is no question that the motor omnibus industry is destined to assume great proportions; and it is equally certain that well-considered enterprises, reasonably capitalised, and established on the basis of approved experiment and trustworthy data, will have excellent promise of success. But the principle that it is not safe to stake money on a class of investments without considering the individual enterprises of which the class is composed has been recently exemplified in the Cycle and Brewery markets, and must not be overlooked. The investing public may not see the bearing of this principle upon the motor 'bus campaign unless the facts are brought to the front. It is to urge the necessity of discrimination, and to point the lesson which we think is enforced by the prospectus of the Motor 'Bus Company, that we have dwelt at some length upon the issue of that enterprise.”

Road Tarring Experiments.—The stretch of tarred road at Byfleet, which was treated last August for the purpose of testing the advantages of tar treatment as a dust preventative, and which we have kept under observation ever since, has turned out a dismal failure in the wet weather. As our readers will remember, the stretch of road treated was that from “Byfleet Corner” down to the Wey Navigation Canal—a distance of about three-quarters of a mile. During the months of August and September the tar proved an effective dust layer, though it had to be frequently brushed clean owing to the “effects” of horse traffic. Since the end of October, however, when the road has been exposed to alternations of frost, thaw and heavy rain, the surface has gone absolutely to pieces and forms a slough of despond not equalled by any main road in the neighbourhood. The remnants of the tar seem to have effectively assisted in the formation of mud, and, needless to say, it is a black mud, the adhesiveness of which has a tremendous effect on increasing resistance to traction. It is only fair to say, as regards the tarring process, that the stretch of road on which it was tried

was always more or less defective. It was originally not well built, it has always been singularly dusty in summer and muddy in winter, though never anything like as muddy as now. It is possible that the tarring on a new road, properly built and properly made up before the tar was applied, would prove more successful. All that can be said at present is that the Byfleet tarring experiment has wholly failed to withstand wet weather.

Dangerous Driving.—We have often poured forth the vials of our indignation on drivers of any kind or description who have ventured to drive on the wrong side of a London shelter. It is about the most dangerous thing that can be done in our streets, for everyone crossing feels convinced that no one will violate the sacred rule and is therefore not looking out for traffic coming in the wrong direction. We are sorry, therefore, that this offence has been committed by the driver of a motor 'bus and we certainly do not think that Mr. Curtis Bennett, before whom the offender pleaded guilty, was at all too draconic in imposing a penalty of 40s. and 2s. costs.

THE OLYMPIA EXHIBITION.

AT OLYMPIA.—Views of the interior and exterior of the new War Office Motor Ambulance Van, constructed by Straker and Squire. A description of this appeared last week.

It is only now, when the great Show has closed its doors—as it did last Saturday night—that a really complete idea can be formed of the extraordinary welcome it has received at the hands of the general public. The interest taken in the exhibits, and the amount of business that was done, has, from all accounts, exceeded the most sanguine expectations of the organisers, while on the other hand, everyone was unanimous in their praise of the efficient manner in which the Society of Motor Manufacturers and Traders conducted their arduous task, and carried their well-considered arrangements through without the shadow of a hitch. The attendance throughout the week was all that could be desired, considerably exceeding that at the previous Exhibition last February.

In our report last week, we devoted our attention almost entirely to the pleasure vehicles and to the exhibits of tyres, leaving over for this further article a consideration of the commercial vehicles, the motor boats, and the novelties of an "accessory" character. We also gave, however, a classified table setting forth the leading features of those commercial cars which were on view, that table corresponding with the comprehensive table of the previous week, when the pleasure cars were similarly collated.

'BUSES AND LURRIES.

Perhaps the most noticeable fact brought to light by the heavy vehicles at the Show was that the majority are propelled by side chains. A special significance is doubtless given to this since hitherto the Thornycroft 'buses have had a single chain, and the Company have had every opportunity of weighing all pros and cons, in the light of recent practice with various transmission systems,

while they were designing the entirely new side-chain model that made its first appearance at Olympia. This latest 'bus chassis has so many special features that we propose to devote a separate description to it, and to their new 1-ton model, next week. The Wolseley 'bus and that of Messrs. Straker and Squire, are both, of course; well-known instances of chain-driven vehicles, and both have—as already described in detail—spring-cushions to relieve the chains of sudden shocks. In the Wolseley case, it will be remembered, the spring-cushions are inserted between the radius-rods and the stationary axle, while the Straker-Squire device consists of volute springs mounted on rods that project rearwardly from the axle. Incidentally, while mentioning

AT OLYMPIA.—The new "one man" 'bus constructed by Straker and Squire for the Great Western Railway Company. All the passengers must enter and leave the vehicle by the steps near the driver who can thus make sure of collecting the fares.

AT OLYMPIA.—Baslow and Bakewell Motor Omnibus Service.—One of the new vehicles supplied to the Derbyshire Motor Omnibus Co. by the Motor Car Emporium, Ltd.

the vehicles of these makers, it may be remarked that Messrs. Straker and Squire are about to introduce another British-built model having a more powerful engine, and a word or two may be said about the body that was shown on the Wolseley chassis. The Straker-Squire engine now has cylinders of $4\frac{1}{2}$ -in. bore, but the 30-h.p. type is to have the bore increased to 5 in. On the Wolseley chassis, the body (designed by Mr. Stanley—lately with the Company at their Adderley Park Works) was particularly strong in relationship to its weight, besides being very graceful in every outline, this result having been largely obtained by the judicious use of steel forgings for bracing it into a rigid structure right up from the main-frame.

Also of the chain-driven type are the quite new models exhibited by the Arrol-Johnston Company, and by the Simms Manufacturing Company, both of which bear evidence of sound design and good workmanship. The former has its chains—which are unusually short—enclosed in aluminium casings, its differential countershaft is carried by the long tubular radius-rods that pass forward from the axle to the frame, and not only is a spring-drive introduced at the rear end of the universally jointed shaft that drives the differential gear, but a transverse spring is used for increasing the effectiveness of the usual side-springs; a parallel-motion device is also fitted between the stationary axle and the frame to relieve the springs and the radius-rods of all lateral strains. The latter chassis—the Simms—has an extremely strong gear-box that acts as a central cross-member for the frame, and its change-speed mechanism, which is operated on the “Mercedes” principle, has jaw-clutches that obviate bringing any of the spur-wheels in and out of mesh with one another.

Chain-driven, too, are the Clarkson, Maudslay, Iden, and Beaufort models, as well as the “S” type chassis shown by the Motor Car Emporium, while the James and Brown ’bus—which by the way has an exposed form of rack-and-pinion steering—is fitted with extraordinarily long chains at each side. On the Clarkson stall, the new double-deck pattern attracted considerable attention, for not only have the Clarkson single-deckers proved eminently successful in various parts

of the country for some little time, but many alterations have been made in the “flash-steam” system, which is peculiar to the larger cars. The generator coils may now be said to be of a volute shape, for each section is coiled into a conical spiral in order to prevent the water—which enters at the top of the generator—from flowing down freely by gravity, and so allowing the generator to empty itself when at rest. The system is rendered even more similar to that of the White steam cars by the use of a thermostat to control the fuel-feed, and an automatic by-pass that causes the steam pressure to regulate the feed-water. On the Iden chassis, which has a transverse spring behind the rear axle and has underframe members extending the entire length, an interesting feature is the clutch, for although it is of much the usual internal-cone type, the leather-faced member has copper friction-blocks that merely utilise the leather as a soft pad. Of the other cars mentioned above in this paragraph, that exhibited

on the Motor Car Emporium stall is in some respects remarkable, since the engine has ball-bearings for the crank-shaft, and it is also equipped with a special mechanism by which it can be used as an air-pump brake.

In several cases these side-chain cars have the foot-brake arranged in such a way that it acts direct upon the two sprockets at the ends of the differential countershaft, two interconnected brakes being thus employed. This is so on the Thornycroft, Simms, Clarkson and Maudslay ’bus chassis; on the last mentioned model these brakes are of the internal type.

On four types of commercial vehicles, including the Milnes-Daimler itself, the rear road-wheels are carried by a stationary axle and are gear-driven, in somewhat the same way as has always been done by the Milnes-Daimler Company. In that case, however, the countershaft carrying the pinions at each end is supported on the long radius-bars that tie the axle to the frame, whereas the latest 1-ton Thornycroft, and the ’bus chassis exhibited by Messrs. Straker and MacConnell,

AT OLYMPIA.—A new double-decked ’bus intended for the “Vanguard” service, constructed by the De Dion Company. The top seats are enclosed, which gives the ’bus an extremely high appearance.

AT OLYMPIA.—View showing one of the Shock-Dampers on the 120-h.p. Fiat Racing Car. Fixed to the main frame is a Brake-drum, A, around which is a Brake-strap, A¹, pressed up against it by an adjustable Spring, A²; the Brake-strap, A¹, is tied to the axle by a rod, B, which is hinged to a lug, B¹, projecting from the axle.

have this countershaft mounted direct upon the stationary axle itself. Very dissimilar also in many respects is the transmission on the De Dion 'bus, for on these cars the differential-gear is carried by the main-frame, and it is only the short cardan-driven shafts that are mounted upon the axle proper. The De Dion main frame, by the way, is made of wood with steel plates clamped firmly at each side, and the Straker and MacConnell engine is equipped with the necessary gear for rendering it effective as a "suction" brake.

Amongst live-axle cars, it was noticeable that horn-plates were in favour with several makers. Such is the case on the Dennis model (which, it will be remembered, has a worm drive), on that of the British Automobile Development Company, and on the Scott-Stirling 'bus. The Dennis has a transverse spring connected with the

side springs, and there are two torque-rods—one on each side of the centre—to tie the axle casing to the frame. The "British" 'bus is quite a new model introduced by a recently formed Company, and its engine has all the valves mounted centrally above the cylinders. As hitherto, the engine on the Scott-Stirling chassis lies beneath the driver's seat, and a clutch of the internal expanding variety is employed.

Another live-axle chassis at the Show was the "Ducommun," exhibited by the Motor Car Emporium, and this had many very unusual characteristics. Although the axle is bevel driven, spur-gearing is introduced between the propeller-shaft and the bevel-pinions, and further than this we noticed that no radius-rods or torque-rods connect the axle with the frame. The engine, too, has its own peculiarities, for there are two transverse cam-shafts passing across between the crank-pins, and these operate all the valves in a very simple manner.

On the score of suspension, apart from such points as have been mentioned above, attention might be drawn to the sliding-pins and other slipper devices used for attaching the springs to the frame, instances of these being found on the Straker-Squire, the Dennis, the Simms, and the De Dion models. There is, too, the leaf-spring hanger of the De Dion Company for connecting the rear ends of the front springs to the frame, and the "Ducommun" 'bus which has its front-spring shackles horizontal instead of vertical. The De Dietrich 'bus has additional side-springs to supplement the usual semi-elliptics.

ACCESSORIES AT OLYMPIA.

THERE is always a fascination about a well-displayed collection of motor accessories, and never have we seen a better, or more representative, exhibition than was held in the gallery at Olympia. It was, as usual, by way of being a side show, and in this capacity had the misfortune to attract the greater proportion of that inevitable

AT OLYMPIA.—Two views—one from each side—of the 120-h.p. Engine fixed in place in the Fiat Racer, which was driven by Lancia this year. A single rod, A, operates the exhaust-valve, A¹, and the inlet-valve, A², of each cylinder by means of a rocking-lever, A³; the valves are held up against their seats by external leaf-springs, A⁴, and there are strong helical springs, A⁵, to press the rods, A, downwards. For cooling the exhaust-valves, the water—which enters the cylinder-jackets by a branched pipe, B,—is carried through a jacket in the valve-housings, from which the return pipe, B¹, conducts it back to the radiator.

varied to suit the internal pressure of the tyre. Between the removal and the re-pumping of a tyre, there is usually some form of repair to be executed, and in this connection attention may be drawn to the portable vulcanisers which were exhibited by Harvey Frost and Co. They are no longer a novelty—in fact, they are now coming into very general use—and this system of repair is already familiar to our readers, but in addition to the small plant for the repair of inner tubes, which has been on the market for some time, this go-ahead firm have now brought out a vulcaniser for use on outer covers; the operation being performed without removing the cover from the rim.

Head-lights.

Lamps undoubtedly add the finishing touch to the appearance of a complete car, and at the present day the best lamps are so well made and so perfectly finished that they are worthy of their imposing position. No exhibit in the whole gallery was more attractive than that of André Godin, who has the agency for the famous

Ducellier head-lights, where almost every conceivable size and shape of motor lamp was on view. The latest model, which is a large, self-contained acetylene head-light, is constructed so that it can be charged with water and carbide, and then left unused, for a month if necessary, without wasting the carbide. One of the troubles of night driving is the difficulty of reading, and sometimes, too, of finding, the signposts, for which purpose the paraffin side lamps are generally inadequate. Those who indulge much in journeys by night, therefore, will probably find an advantage in having one of the small acetylene lamps which were shown by the United Motor Industries, for it is constructed with a swivel attachment which enables it to be permanently mounted above the dash, and yet renders it possible for a powerful beam of light to be projected in any direction at will.

Speed-Indicators.

Motoring as a pastime is so much enhanced by the possession of a speed-indicator that it is not surprising to

AT OLYMPIA.—View of the Anglo-American Oil Company's Stall. On the right, in the glass case, is a magnificent model of ss. "Narragansett," one of the steamers which bring Pratt's motor spirit to this country. This boat is the latest addition to a fleet which is owned by the Company, and some idea as to the magnitude of the oil trade—in which petrol is a factor of ever-increasing importance—may be gathered from the fact that this ship alone has a tonnage of 10,500, and a tank capacity of three million gallons.

crowd of evening sightseers whose interest in automobilism is mainly confined to the surreptitious blowing of horns wherever and whenever it gets an opportunity. Luckily for the peace of other stallholders, however, those who displayed motor horns mostly kept the operative part on their own side of the counter this year, where it was well out of the way of an easily-tempted public. With one or two exceptions, therefore—notably the case of a new kind of motor wind instrument, which gave forth its variegated notes upon the least provocation—such exhibits were no longer the nuisance that they have been known to be in the past. Each year brings its batch of novelties, and on this occasion there was an exceptionally good show of new inventions, many of which appeared to be *bona fide* attempts to supply long-felt wants.

Tyre Repair.

Tyre repair forms such an important feature of motoring that accessories connected with the art deserve close attention, especially if they are designed, as are the new levers brought out by Lacoste and Co., to facilitate the single-handed removal and replacing of tyres. These levers are very ingenious, and although they may not appeal so strongly to the expert—who always prefers few tools to many—they at least reduce the manual labour to an extremely small minimum, and even if somewhat slow, they are at all events sure, so that anyone might tackle a very stiff tyre single-handed with every chance of easy success. Pumping up a tyre is under any circumstances a laborious process, but many motorists must have thought that it would be more endurable if only the pump itself could be got into a more convenient position, or were made in a form less liable to produce backache. With the idea of overcoming these drawbacks to the ordinary plunger pump, the United Motor Industries have put on the market a new model which is operated by rotating a crank. It is a compact appliance, and it is constructed so that it may be instantly attached to brass clips which are permanently fixed to some convenient place on the car. In order to make it easier to work, the crank-handle is adjustable so that the leverage may be

AT OLYMPIA.—The Stand of the Continental Tyre Company, which was unique by reason of the huge tyre model which was erected extending across a large portion of the exhibit.

find that such a firm as S. Smith and Sons, the famous watchmakers, have fitted fifteen hundred of their well-known indicators during the past six months alone. Moving with the times, too, they have this year introduced a new instrument combining a speed-indicator, speed-recorder, and eight-day clock. It is one of the neatest devices of its kind which we have seen, is compact, useful, and not too obviously a tell-tale; for the little chart is inside the case, where it is perfectly accessible to those who know, but well out of the inquisitive's sight. Lacoste and Co. also introduced a new speed-indicator—the "O.S."—of what may be termed the "Foucault" type, for it operates by reason of the eddy-currents induced in a copper disc by the rotation of a permanent magnet. We hope to be able, very shortly, to include a description of this instrument in our series of articles on Speed Indicators, but for the moment it will suffice to say that it is extremely compact and of very neat appearance, as, indeed, all dashboard fittings should be. There was another new speed indicator on Davenport and Co.'s stall, which differs in action from the ordinary types, in that it does not perpetually indicate

implements displayed by the numerous assistants—all of whom, it may be remarked, have a personal interest in the business. Practically everything that is worth its place, either of English or foreign manufacture, finds its way to this famous house, for Mr. Melhuish makes frequent tours abroad, as well as nearer home, in search of novelties for the English market, and rarely returns without something of real value. For motorists' use, the speciality of this firm is a leather hold-all, which is fitted with a variety of useful tools, and is ingeniously constructed so that each is independently secured by the same straps which fasten the ends of the leather case. One of the recent additions is a strongly-made little vice, specially constructed for attaching to the step, and for those who have a workshop of their own, the light adjustable stock for holding any size of screw tap is a distinct improvement on the old type.

Electrical Accessories.

One of the most pleasing novelties this year was the electric telegraph on Messrs. S. Smith and Son's stall. Such an instrument is, of course, only really required by

AT OLYMPIA.—Messrs. Melhuish's "Branches" at the Exhibition. On the left is a view of the stall in the Gallery, where this old-established firm displayed a wonderful collection of small hand-tools, and on the right is their other stall in the Annexe, where the machine tools were shown.

the speed of a car, but can at any time be brought into operation by pressing a button on the case. In principle, too, it is unusual, for the speed is indicated by measuring the distance travelled in a given time. One of the chief advantages claimed for it is that it enables an exceptionally slow drive to be employed. As at present constructed, the flexible shaft is driven by a worm and wheel, and the indicator is combined with a clock—the same dial being used for both purposes.

Tools.

Of all the accessories which a motorist carries on his car, his tool kit should be the most perfect, for that alone has greater capabilities for saving his time and temper than anything else. In the motor world, or, indeed, outside it, no firm of tool merchants is better known or more widely respected than Messrs. Melhuish, who opened what was, both in size and equipment, practically a branch establishment in the gallery during the exhibition. It would be quite impossible to give any idea of the vast collection of tools which were on view, but certain it is that almost every visitor stopped to look and most of them stayed to buy, so well were the various

those who travel in enclosed carriages; but for them it is in the nature of a necessity, and quite a number of the cars in the main hall were, we noticed, fitted with it. The latest model has a very complete set of signs, such as "stop," "faster," "1st to the right," and so on, and the connections are so made that when the button is pressed slightly a red lamp is illuminated against the required sign. Should the driver fail to notice it, however, his attention may be attracted by pressing the button harder, which rings an electric bell.

Ignition is not yet so entirely accomplished by magnetos—although the large number of these machines employed, notably of the Simms-Bosch type, was a feature of the Show—that motorists have lost their interest in accumulators and the attendant electric equipment for this type of ignition. On Van Raden and Co.'s stand were the extremely interesting woven glass accumulators which this Company manufacture at their Coventry works, and, as usual, there were also several little novelties in the way of pocket voltmeters and the like, which are especially useful to motorists. One of these, in particular, attracted our attention—it was a small voltmeter and ammeter combined in a neat wooden case.

When closed, there is no outside terminal of any description, for the flexible lead, common to both instruments, winds up on a spring drum, and the stationary terminals are recessed below the level of the wood. The case is provided with a swivel lid, however, which, when opened in one direction projects the terminal of the ammeter, but when turned in the other direction brings the voltmeter terminal into use, thus making it impossible to employ the wrong one, provided that the case is opened correctly.

Fuel and Lubrication.

There are two things which a motorist must take very much for granted—his fuel and his lubricant. Both, however, are of the very gravest importance to the well-being of his car, but neither of them appeal very directly, at an Exhibition, to the actual user. And yet two of the most interesting shows in the whole of Olympia were the stalls of the Anglo-American Oil Company and the Vacuum Oil Company—the former controlling the deservedly popular Pratt's Motor Spirit, and the latter the equally famous Vacuum lubricating oil. What would have appealed to anyone visiting the stand of the Anglo-American Oil Company, however, was a magnificent model of the ss. "Narragansett," the latest addition to the company's large fleet of tank steamers. It is registered for 10,500 tons, and will carry no less than three million gallons of oil in its enormous tanks. In addition to this model were several excellent photographs of the extensive works where the petrol is stored and canned ready for the consumer, while specimen glasses showed the uninitiated at a glance each stage in the evolution of petrol from crude petroleum. It was an interesting show, and it gave the motorist an excellent opportunity of making a bowing acquaintance with the spirit which he uses so freely, but as a rule professedly knows very little about. No less interesting, and of a very similar kind, was the stall of the Vacuum Oil Company, where the inquisitive

might see tubes full of liquids, some translucent, others densely opaque. One and all, however, are for the same purpose—to reduce friction—and each does its work by the same means—the interposition of a liquid film between the sliding surfaces. And yet there is all that difference between the various oils, and the average motorist may well be excused if he draws the line at forming a too definite opinion of his own on which he should use. That is indeed the wisest conclusion at which he can arrive, for lubrication is a field for experts only, and the safest plan is to trust to the recommendations of such men. No firm has given more attention to the requirements of the motor industry in this respect than the Vacuum Oil Co., and the result of their experiments has been a range of standard oils which meet the requirements of all the cases with which they have yet had to deal. Motorists are principally acquainted with three of these, which have hitherto been known as "No. 1," "N," and "No. 2," but will henceforth be called "A," "B," and "C," respectively. The first (A) of these oils is for multi-cylinder engines, the second (B) is for single-cylinder engines, and the third (C) is for enclosed gearing. "No. 3" and "Heavy R" remain under the same names.

MOTOR BOATS AT OLYMPIA.

THERE were more boats shown this year than on any previous occasion, and they occupied quite a large portion of the annexe. On the whole, however, it is questionable whether, as the representative exhibition of motor craft, it was a really successful show, or, indeed, ever will be so long as it only forms such a minor part of another exhibition. Visitors at Olympia chiefly went to see the cars, and if they took a look at the boats, in passing, it was not generally with a very definite idea of purchase. Some seemed to think it too early, and others, more interested in river launches, were doubtless deterred by the effect of the new regulations which now so greatly hamper the users of pleasure craft. In fact, the laborious edicts of the Thames Conservancy appear to have put motor boating on the Thames under a pall which may be likened—having due regard to present circumstances—to that which overshadowed the "pastime" of motoring before the Act of 1896. Neither was there any great parade on the part of the manufacturers of their having constructed the equipment of their boats in accordance with the technical requirements of the Conservators, as laid down in the new bye-laws. Several of the principal exhibits were, as a matter of fact, the actual boats entered by the respective firms in the Motor Yacht Club's Reliability Trial, but these are, of course, constructed with a view to possessing some sea-going capacity, and are not altogether of the kind which find favour on the river.

For those who really visited Olympia in order to acquire a motor boat there was an excellent selection, even although several well-known firms were absent. Quite a range of sizes, too, was available, the smallest being the Mitcham Motor Company's little 12-ft. dinghy, fitted with a 1-h.p. F. and B. engine of the two-stroke type, and provided with a reversible propeller. For thirty pounds, the modest "would-be" motor yachtsman could thus have started his nautical career as owner and skipper of a self-propelled boat. Those aspiring to something more substantial, and anxious for a deck to pace, had an excellent opportunity of judging the merits of the equipment of S. F. Edge and Co.'s famous Napier

AT OLYMPIA.—A 100-h.p. marine engine constructed by the Simms Manufacturing Company. All the valves are above the cylinders under the domed covers shown in the photograph, and a single cam-shaft passing across the top is employed to operate them.

AT OLYMPIA.—Panhard II. in her tank. This boat is built on the Saunders principle and has a three-cylinder 8-11-h.p. Panhard engine with the new Saunders reverse gear. Her sister boat, Panhard, was shown by J. E. Hutton, Limited.

Major. Indeed, this boat was unquestionably the *pièce de résistance* of the annexe, and, as a side show, it offered more attractions and less obstruction than any other in the building. She has remarkably good lines, even out of water, when most boats appear ungainly, and of course her sea-going capabilities are now so widely known, through her recent voyage to the North, that further reference to them would be superfluous.

Racing boats seem to obtain a greater individuality through their successes than do racing cars, probably, it would seem, because they are endowed with names of their own. Thus there was a sense of recognition in seeing Dietrich II. on Jarrott and Letts' marine stall, although it is, we believe, the first time that this boat has hitherto crossed the Channel. She is an interesting craft, and remarkably roomy too, for a fast cruiser. Built on fine lines, the engine is placed well forward under a hurricane deck, so that the propeller shaft is nearly horizontal. It was interesting to compare the propeller on Dietrich II. with those shown on the Thornycroft stand. Each represents a distinctive type, and although there is no unanimity in propeller design—nor any likelihood of it under the present confusion of ideas—yet the narrow tapered blades of the Dietrich II. propeller are essentially French at the present time, just as the squat oval lines of the Thornycroft propeller may be justly accepted as the prevailing British type, merely because it is the product of that famous firm. Many and various are the "designs"

of propeller which inventors devise, in the fond imagination that they will revolutionise marine propulsion; there have been propellers which utilise only the tips of blades set on the periphery of an enormous boss, and others in which the blades are reduced to practically nothing but their roots. Each type has had its advocates, who have invented elaborate mathematical proofs of the perfection of their own ideas. At Olympia there was also a new propeller, which we do not recollect having seen in a material form before; it is the invention of Dr. Truss, and is quite different to those of orthodox form. Owing to the absence of any representative on the stall who knew anything about it, however, we are unable to give the inventor's ideas on the subject at the present time, but it is apparently designed on the principle that a complete helix is likely to be more effective than merely part of one, and the two "blades" are, therefore, continuous

like the thread of a screw, each making a complete convolution about the boss. At each end the blades taper down towards the axis, so that when revolving the propeller would have a spherical appearance.

There has been a large amount of originality, too, in the construction of hulls for small boats, while, of course, the design—having always to suit some particular case—is seldom twice alike. This year the pressed-steel boat shown by the Seamless Steel Boat Company was an interesting novelty, although pressed-steel boats are not, in themselves, new. Each side of the boat is pressed from the sheet, and the edges are joined by riveting to a bulb girder forming the keel. Enormous machinery must be used for this purpose, yet boats are, we understand, made in this manner up to 50 ft. in length; it is unlikely, however, that the construction will become generally used—although it has great merits for tropical climates and is immune from damage through fire—because once the "lines" and sections of each standard length have been decided upon, they have to be adhered to for all types of craft on account of the great expense of making different dies. Corrosion is popularly supposed to be a drawback to steel hulls, but this is, as with any other metallic substance in water, merely a question of paint.

Another boat having a steel hull was shown by Meinhardt and Co. It was a cruising cabin-launch 35 ft. long, made of Siemens-Martin steel, with flush-joints and countersunk rivets. In appearance, therefore, it could not be detected from a well-finished, carvel-built

AT OLYMPIA.—De Dietrich II.—The high-powered racing launch, fitted with a De Dietrich Engine, which has, during the past season, given such a good account of itself in Continental waters. This boat is in the Marine Section of the Olympia Show.

AT OLYMPIA.—Component Parts of a Thornycroft 24-h.p. Marine Set, showing the Engine coupled up to its reverse gear, with the Petrol Tank, Silencer, Propeller, and other important parts alongside.

wooden hull. Quite one of the best known forms of construction is the Saunders system, in which the diagonally arranged timbers are sewn together with copper wire. It makes an extraordinarily sound job, and being somewhat flexible as a whole, is not easily damaged by shock. Panhard II., a graceful launch, which floated in a large tank on Panhard and Levassor's stand, is built on this principle, and is the latest product of the Saunders yard. Placed well forward, the 3-cylinder 8-11-h.p. Panhard engine is set as low in the hull as it is possible to get it, in fact, the hull section at this point is largely governed by the dimensions of the engine, although it does not go so far as to form a distinct trough in the way that was done on Lord Howard de Walden's racer, "Napier." Aft, the floor runs up to the water line, and a good sized propeller has been fitted without unduly sloping the shaft. Panhard, the sister boat, was exhibited on J. E. Hutton's stall.

For those who require a good open cruising launch, the Thornycroft boats were excellent examples, but as they were actually part of the Thornycroft "fleet" in the Reliability Trials, and were described by us at that time, further reference is unnecessary. On the Wolseley Company's stall, too, was a fine mahogany cabin launch, 35 feet over all, and fitted with a 50-h.p. Siddeley engine—altogether a powerful, roomy craft for general use.

Another cabin launch worthy of special mention was the 25 foot Brooke boat, which was remarkable for its extensive accommodation compared with its size. Constructed of teak, the cabin is placed forward under a raised hurricane deck, similar to that used on the Brooke racer, so the boat is well designed with a view to being useful in all weathers. As then equipped, it had a 3-cylinder 12-h.p. Brooke engine, but, as a type, the hull seemed suitable for more powerful machinery if required. Of small moderately-priced boats there was a fair selection, but those on the De Dion Company's stand were particularly attractive; since one of them figured in the Reliability Trials, they are already familiar, for the other was almost a sister boat, differing only in length and in having a mahogany hull.

Marine petrol engines are receiving more and more attention from automobile engineers, and several well-designed sets are now on the market, notably the Yarrow-Napier, Iris, Thornycroft, Blake, Fiat, Gardner, Parsons, Scout, and Buffalo. Among the engines of larger power were the Yarrow-Napier, Simms, and the Ailsa Craig. On the Simms engine is a very accessible construction of overhead valve gear, while the peculiar features of the Ailsa Craig are the tangential setting of the cylinders relatively to the crank-shaft, and the square water-jackets. Although not peculiar for high power, the Thornycroft gas engine (Capitaine system) was perhaps the most interesting of all, not only because it uses suction-producer gas, but also because of its original construction.

Much attention is now being given to the design of compact and efficient reverse gears. Thornycrofts have designed a new type of their own, and Messrs. Saunders have introduced a most ingenious device which, while being, *au fond*, of the epicyclic type, combines a system of metal cone and positive jaw-clutches for the purpose of preventing slip, and is also so arranged that it is impossible to introduce the reverse before the propeller has stopped rotating. Owing to the difficulty of obtaining reverse gears to suit the various sizes of their engines, Messrs. Gardner have this year made their own; it is of the epicyclic type, operated by internal expanding and external brake-bands, but its features are rather in the nature of strength and reliability than in originality of construction, although the cam action for working the clutches is ingenious and simple.

AT OLYMPIA.—View of the "Capitaine" Gas Engine, constructed by Messrs. Thornycroft and Co. for marine purposes. The engine is of an entirely novel design, but its principal features, as also those of the "Capitaine" Suction Producer, have already been described by us. A two-cylinder engine of this type was exhibited at the Show.

The Automobile Club Annual Dinner, in the Great Hall of the Hotel Cecil, on Friday, November 24th, when the Hon. Arthur Stanley, Chairman of the Club, presided.

THE A.C.G.B.I. ANNUAL DINNER.

THE Annual Dinner of the club took place in the large hall of the Cecil Hotel on Friday, November 24th, the Hon. Arthur Stanley, M.P., presiding. Accommodation was provided for 564 guests, all of whom, with a few exceptions, were present, including the following:—His Excellency the United States Ambassador; the Right Hon. Lord Suffield, G.C.V.O., K.C.B.; Major-Gen. Sir L. J. Oliphant, K.C.B.; Col. H. C. L. Holden, R.A.; Prof. von Herkomer, R.A.; His Excellency the Greek Minister; Mr. Arthur Lee, M.P.; His Excellency the Chinese Minister; the Right Hon. C. Stuart-Wortley, P.C., M.P.; Sir Boverton Redwood, D.Sc.; Sir Albert Rollit, M.P.; Lieut.-Col. Mark Mayhew; the Right Hon. Earl Russell; Capt. Sir T. C. Wroth Lethbridge, Bart.; Messrs. A. F. Bird, Hardinge Cunynghame; Major-Gen. F. W. Benson; Major F. Lindsay Lloyd, R.E.; Brig.-Gen. Ruck; Sir F. Dixon-Hartland, Bart., M.P.; Messrs. R. Hancock, E. Manville, R. S. Erskine, Frank H. Butler, H. Favarger, G. C. Ashton Jonson, J. F. Ochs (vice-chairman), V. Ker-Seymour, H. Weguelin, E. K. Purchase, J. S. Mallam, Frederick R. Simms, Comte de Lavallette, General Becker, Mr. W. Rees Jeffreys, Sir Edgar Boehm, Bart., Messrs. E. M. C. Instone, Dugald Clerk, T. H. Woollen, the Hon. C. S. Rolls, Messrs. C. E. Shaw, Stanley Spooner, W. Ballin Hinde, Lord Royston, Messrs. Frederic Coleman, Walter White, J. A. Holder, Col. Challoner Knox, Lieut.-Col. Fox, Messrs. T. G. Chambers, F. S. Philipson-Stow, J. S. Critchley, Colonel Kinloch, Messrs. J. D. Siddeley, W. B. Gentle, Lyons Sampson, G. T. Langridge, Claude Johnson, Dr. Charles Firth, Messrs. R. E. Phillips, T. W. Grace, Robert Todd, S. Straker, Sidney Smith, Captain G. H. Dean, Messrs. R. J. Smith, J. R. Nisbet, J. Allan Baker, M.P. (Chairman Highways Committee, L.C.C.), Sir Hiram Maxim, Mr. W. Worby Beaumont, Dr. P. P. Whitcombe, Messrs. C. D. Rose, M.P., E. H. Cozens-Hardy, J.P., Major Kingsley Foster, J.P., Mr. F. P. Armstrong, and Mr. J. W. Orde (secretary).

The loyal toasts having been duly honoured,

Sir Boverton Redwood, in proposing "The Navy, the Army, and the Auxiliary Forces," announced that the Duke of Sutherland had consented to assume the position of Commodore of the Motor

Yacht Club. The club had obtained the use of the late Admiralty yacht "Enchantress," which would be moored in Southampton Water as a yacht house, and they were hopeful of being able to bring about the formation of a marine corps of motor volunteers, who might be of use to the Navy in time of war.

Mr. Arthur Lee, M.P. (Civil Lord of the Admiralty), in returning thanks, paid a well-merited compliment to Sir Boverton Redwood, who, he said, was their main lubricator, and one that was not constructed on the forced-feed principle, because he had always given to them his valued services ungrudgingly and without remuneration. He said there was one direction at least in which the motor engineer could render great and much-needed service to the Navy. He referred to the internal combustion engine for naval purposes. If they could design and produce a heavy oil engine which would be capable of being easily started, and would be easily reversible, without the introduction of compressed air, if possible, which would be fairly silent and free from complications, they would have supplied what was a keenly-felt want in the Navy. They wanted engines of this kind, from 50 to 300-h.p., for the auxiliary machinery of their ships, their picket boats, and launches; and if they could produce a heavy-oil engine, with sufficient power per cylinder to replace the 7,000-h.p. engines of the destroyers, and the 30,000-h.p. engines of the "Drake," for instance, the Admiralty would gladly build them to their design and give up steam for ever. In so doing, over a million sterling a year in the wages of stokers alone would be effected, besides many other acceptable economies.

Major-General F. W. Benson, responding for "The Army," thanked the members of the Motor Volunteer Corps, who had always come forward in the most patriotic manner to help them, and practically teach them, the value of the motor for the training of troops in the peace manoeuvres. They had now their Mechanical Transport Companies, and they had a Mechanical Transport Committee, which sat constantly at the War Office, and investigated all new inventions; they had a School of Instruction at Aldershot, where they turned out as good drivers for the Army Service Corps as the Army could want to have. They had set up works at Aldershot, and carried out their own repairs, and anyone who witnessed the last manoeuvres at Aldershot must have seen their travelling workshops executing all the repairs which were necessary

at that time, and doing the work most efficiently. If the Motor Volunteer Corps increased so much that they had 5,000 motors, it would represent a very formidable and efficient force to assist in repelling any raid or invasion that might happen.

Lieut.-Col. Mark Mayhew, who responded for "The Auxiliary Forces," said in regard to Major-General Benson's suggestion of a Motor Volunteer Corps of 5,000 members, that he only hoped that the War Department would some day give them an establishment like that, and that the Automobile Club and the Motor Union would be good enough to fill it.

Mr. Alfred Bird proposed the toast of "The Houses of Parliament," and said, by the law which the House of Commons passed in 1903 one of the most Gilbertian positions had been created, as it had furnished them with a set of magistrates without number appearing in the dock: Without being in court to sentence offenders, they were there as offenders themselves to be sentenced. He had great hopes as to the results likely to ensue from the Commission now sitting, who, he felt confident, would bring out a report on which a workable Act of Parliament might be based, and he was sure they could count on the same measure of fair play for automobilism in the House of Commons which they could count on from any other body of Englishmen.

Lord Suffield responded for "The House of Lords."

Mr. C. B. Stuart-Wortley, M.P., in responding for "The House of Commons," said that Parliament would do well to leave the automobile to what the late Sir William Vernon Harcourt used to call "the masculine sense of common law." The automobilist who had shown all possible care for himself and other users of the road, and had avoided, as far as possible, all danger to the public, and who, nevertheless, was found to be travelling at about 20½ miles per hour, was a person who has not been left in a satisfactory position by the law as made in 1903. He hoped that the Parliaments of the future would not be blind to the interests of the automobilist, and to the progress of science and the irresistible march of a great people towards constant improvement. He trusted that it would occupy itself by considering this problem to the exclusion of less useful, though, perhaps, more ambitious schemes.

Sir Albert Rollit, M.P., in proposing the toast of "The Club," recalled, in his happiest vein, some amusing stories. The "road-hog," he said, was an individual whom they need never help or support; the "scorcher" was a debaucher of true pleasure. The "scorcher" was more dangerous on the road than the ancient high-

wayman. The highwayman, at least, gave an alternative. He said: "Your money or your life." But the scorcher did not give a choice.

The Chairman (the Hon. Arthur Stanley, M.P.), in acknowledging the toast, said that he should like to alter his estimate of a few days previously of two millions sterling as the amount of orders already placed for cars for the next four months to about four millions. He said that the Automobile Club not only existed itself, but had created strong bodies in the Motor Union and the Auto-Cycle Club, and last, but not least, the Motor Yacht Club. All these organisations were working in conjunction with the club with a single mind towards the advantages of the great motor movement of the country. They were in close alliance with the Society of Motor Manufacturers and Traders; and he took that opportunity of congratulating that Society most heartily on the great success which had attended their show this year. After referring to the enormous amount of work done by the Club Committee, with its sixteen sub-committees dealing with most intricate and most technical subjects, all run by gentlemen who gave their time and services voluntarily to the cause without reward, and, he was afraid, often without praise, he expressed the hearty appreciation which they all felt for the services of their excellent and indefatigable secretary, Mr. Orde.

Mr. James F. Ochs, Chairman of the House Committee, proposed "The Guests."

Mr. Whitelaw Reid, the American Ambassador, who, on rising to respond, was received with three times three, said he should like to see the policeman, who so carefully looked after the occasional automobilist who tried to run a few seconds under time in going on a clear road where there was no possible obstruction or danger to anyone, give a little more attention instead to teaching *everyone* on the road the law of the road, to the carter who meanders along with his horse on the wrong side of the road, and to the carts with big loads of hay bulging out from either side which persistently took the middle of the road and held it. He was equally averse to the drunken or crazy chauffeur. The oftener the police arrested that man, and the harder the magistrate punished him, the better for every man who used an automobile, and certainly the better for the Automobile Club. No matter whether they were maniacs or irresponsible, they were enemies of the whole cause of the automobile.

Earl Russell proposed "The Press," and "The Chairman" was in the safe hands of Col. H. C. L. Holden, R.A.

MOTOR UNION ANNUAL DINNER.

THE First Annual Dinner of the Motor Union of Great Britain and Ireland took place on Wednesday, last week. The Hon. Arthur Stanley, M.P. (Chairman of the Motor Union), presided, and the list of guests included the following:—

Field-Marshal the Right Hon. Earl Roberts, President of the Berks A.C.; Marquis of Ailsa; Vice-President of Scottish A.C.; Lord Suffield; Earl of Leven and Melville; J. Fletcher Moulton, K.C., M.P.; Col. R. E. Crompton, C.B., Chairman Motor Van and Wagon Users' Association; E. Manville, M.I.C.E.; Sir J. Thornycroft, F.R.S.; Hon. C. S. Rolls; W. Worby Beaumont, M.I.C.E.; S. Straker, President of Society of Motor Manufacturers and Traders; Col. H. C. L. Holden, Vice-Chairman of the Motor Union; A. P. Maybury, County Surveyor of Kent; Claude Johnson; E. M. C. Instone; Chas. Hardy, President Notts A.C.; Major Portal, Chairman Berks A.C.; Capt. Cole, J.P., Lincs. A.C.; G. T. Langridge, Chairman, General Purposes Committee Motor Union; R. J. Smith, Hon. Sec. Scottish A.C.; R. W. Buttemer, Hon. Sec. West Surrey A.C.; F. B. Cawood, Hon. Sec. Sheffield A.C.; Booth Granger, Hon. Sec. Nottinghamshire A.C.; W. Rees Jeffreys, Sec. Motor Union; C. M. Kenyon, Hon. Sec. Kent A.C.; W. L. Lorkin, Hon. Sec. Southern Motor Club; Dr. C. K. Moseley, Hon. Sec. Eastern Counties A.C.; Capt. D. Hughes Morgan, Chairman North Wales A.C.; F. Miéville, Sec. Sussex County A.C.; A. Roberts, Hon. Sec. Blackheath A.C.; T. H. Ryland, Hon. Sec. Midland A.C.; P. A. Sharman, Hon. Sec. North Herts A.C.; Chas. Smith, Hon. Sec. North London A.C.; F. Straight, Sec. Auto Cycle Club; Col. W. Waring, Hon. Sec. Berkshire A.C., Reading; Dr. J. Hopkins Walters, Vice-Chairman, Reading; and the following members of the Committee:—E. H. Atchley, R. W. A. Brewer, H. A. Cunis, R. S. Clifford, jun., A. A. Dale, A. Scrase Dickens, C. H. Dodd, F. Donnison, C. A. Elgood, E. Faithfull, W. Ballin Hinde, A. B. Hearn, G. C. Ashton-Jonson, T. E. King, Capt. L. A. Kingston, W. J. Leonard, D. Mackenzie, A. McAlpin, J. R. Nisbet, A. E. Newton, Col. Parrington, Dr. E. L. Kowe, Stanley Spooner, J. D. Sideley, G. F. Sharp, F. Smith, V. Ker-Seymer, O. Thompson, O. P. Type.

An excellent dinner having been disposed of, and the loyal toasts being duly honoured,

Mr. Fletcher Moulton, K.C., M.P., in proposing the toast of the evening, "The Motor Union of Great Britain and Ireland," said he was qualified for doing so upon the ground that he, as an ardent, but extremely unpatriotic and lazy motorist, was too delighted to find that this was a body of 10,000 people hard at work protecting motoring, and saving him the trouble of doing anything in that way. He was well enough versed in the currents which sway public life nowadays to know that to defend a sport which commenced, not by being most agreeable to the world at large, but by being strictly limited to those who were wealthy was no easy thing; it required a good deal of democratic support to free it from danger. The body he was addressing was, indeed, thoroughly democratic, and it had 10,000 members. It was a democratic body because motorism itself had become democratic. The days when none but the wealthy took an interest in it were long gone by. When he suddenly found his cab stopped for a moment in the street because a pushing motor 'bus had caught it up from behind and was running on ahead, he put up with the inconvenience, feeling that that crowded 'bus contained nothing but converts to the advantage of motor locomotion. And when in the country constituency which he represented, he heard the country doctors discussing as to what was the best motor to be out in all weathers and at all hours, he said to himself motoring is becoming recognised, not only as a plaything, but as a very serious part of life. The world realised the advantage of a servant like the motor, which, so long as he had got no work to do, passively maintained his fast without a grumble. Well, motorism then had shown itself to be useful not only to the far-seeing people who realised what its capabilities were, but to that far larger class of people who did not appreciate a new invention until it had come within the sphere of their own life, and they had felt its advantages themselves, and then they became more tolerant towards it, which was a stage towards enthusiasm for it. The same cycle was passed through with regard to the introduction of the bicycle. At first "the scorcher" rendered it quite as unpopular as the motor was

three or four years ago. This was illustrated by the man who went to insure his life, and had a long list of extremely searching, impertinent and unpleasant questions put to him in order to see whether his life was a life which such an extremely respectable office could accept, and he was answering them with more or less success when the question was put, "Do you ride the bicycle?" Triumphantly he said "No!" "Ah!" said the doctor, passing him back his proposal, "we don't insure pedestrians!" Jokes like that showed that cycling to the quiet, non-cycling public was a terror—a terror such as motoring was a few years ago. But as soon as cycling became a national sport—when, whenever you were motoring on a Saturday or Sunday, you saw clusters of bicyclists looking exactly like meteoric stones, which cluster together to form comets' tails, and go through endless space, it showed you that it had become an enjoyment of the people, and one which they were prepared to protect by their influence. And so with motoring. Motors were in every form becoming useful, not only to a small class, but to the people at large. The task of the Motor Union was, however, not a light one—the victory was not gained. The motor industry, and motoring itself, was at a very critical period of its existence. The Act of Parliament obtained some two years ago was an extraordinary achievement at that time. He thought that motorism got that extremely favourable law, not because it was well known, but because it was so little known that it was able to get that passed without the opposition, which at a later period it certainly had met with, and would meet with. The influence of bad legislation was not to be despised. In his time he had seen two great industries leave England through bad legislation. One was the electrical industry; the other was the motor industry. While other people were allowing motor cars, and getting hold of an industry which now had an output of many millions in this country, we were allowed to go on a motor car provided we went at three miles an hour, and had a man with a red flag ahead of us. And the influence of bad legislation on the motor industry was only very partially undone even at this present day. There had been a Commission appointed to decide what the form of the new Act should be, but it would require a very considerable amount of unanimity in Parliament to pass any new Act, and if no new Act of Parliament was passed, they would get back to a state of things which he was sure the whole of the Motor Union would consider deplorable. Being such a critical moment, he felt inclined to try to give them a little bit of advice. He was a motorist, and he thought motoring magnificent; but he thought it looked rather best from inside. It was extraordinary how unanimous people inside motors were about the pleasure of motorism. He did not find the same unanimity on the part of people who were outside—the people who were in the streets; and, after all, although the fact that there were 10,000 members in the Motor Union cheered his heart, yet, being accustomed to count the number of voters in various parts of England, he did not feel that they had a majority of the constituencies with them. He felt, therefore, that they must realise that there were not legitimate, but comprehensible grounds for their not being very popular. And he wanted them to feel that in their efforts they must realise the necessity of considering, sympathetically, the objections that were made by the public at large to the use of motors. He said that in their own interest; but he thought he should have appealed to a higher interest than their interest, for his belief was that nobody who managed his motor as a gentleman occasioned any inconvenience to others, excepting by the dust he made. He did not believe in a well-managed motor being either a terror or an injury to the general public. He confessed that on a dusty day, when he was anxious to keep and cherish the idea that his existence was on the moral plane, he never looked behind his motor. He did not like his secret sins brought to the light of his countenance, and he must leave it to some ingenious member of the Motor Union to devise some means to lessen that which was an unmitigated nuisance to the world at large, and which, so far as he could see, was essentially bound up in motoring in every country which had a climate worth motoring in. They must be prepared to make concessions without sacrificing principle. For instance, in regard to drivers. That people should take on themselves the responsibility of driving, whether they were professional drivers or gentlemen, without having gone through the requisite study and practice was a thing which ought not to be defended, and which, for the safety and comfort of the public, ought not to exist. Then there was the great question of speed limit. While he did not think it wise or sensible or effective to have a speed limit, on the other hand he did trust that those who represented them would not try to push principles so far as to suggest that the authorities should not have power to put a speed limit where the population or traffic was dense. He thought they would best succeed if they fought for no limit in the open country, but very free powers to local bodies, with the permission of some central body, such as the Local Government Board, to make by-laws

limiting the speeds. Subject, however, to the harmless provision that any such by-laws should last only for three years, and then should require to be renewed. For this reason. Motors were improving rapidly, and they could plead, therefore, that it would be wrong to have hard-and-fast limitations which could not be changed when the improvements were being made so fast. His real reason for wanting this provision was because he was certain that the fears of the public would pass away when they became accustomed to the matter. The public were like the horses, who, meeting the first two motors they shied, but the third they took no notice of. The public, in the same way, as they got more accustomed to the motor, would have less and less fear of it. He would advise them to avoid as far as they could everything being enacted in the statute. It should be left in a flexible and changeable form of regulations made by the local body, and frequently reviewed. He thought then that within a few years they would look back to the rigorous conditions under which they now motored with something like the scorn with which they now looked back on the three miles an hour and the man with the red flag in front. A great number of people were anxious to get rid of the speed-limit, and have only the condition that there should not be driving to the public danger. In regard to this the real difficulty was not the legislation, but its administration. And he regretted to say that the motor question had shown that there were men entrusted with the administration of the laws of this country who allowed themselves to be the victims of prejudice instead of sternly and impartially carrying out the law. Care should be taken that in trying to get free they should not hand themselves over more and more to the mercies of such people. To leave the question of driving to the public danger to be decided by a constable, was very much worse off than having a speed limit. For instance, no one would say that a disabled motor was going at 20 miles an hour; but a man might say, "It is driving to the danger of the public." And if you were at the mercy of evidence which was often given under prejudice, and accepted under prejudice, it seemed to him that a change of words made no difference. In the reforms they wanted there must be not only legislative reform, but there must be administrative reform. No fines inflicted by any bench of magistrates should in the least go in relief of the rates. The question of whether there was driving to the public danger should be made clear by legislation. Every Court ought to be obliged to take evidence as to what was occurring at the time, and the Court decide as to whether or not the driving under the circumstances was to the public danger. It should not be for a policeman to come and say "You were driving to the public danger." That was for the tribunal to decide. He had only to say what the facts of the case were, and the Court had to form its opinion on that evidence; and if they could compel that to be carried out, and they had a short and summary and practicable appeal as to whether the evidence given supported the finding, he thought the number of scandalous prosecutions would be diminished tenfold. In legislation he advocated avoiding, above everything, stern limits being fixed by an Act of Parliament. It was difficult to get Parliament to take time to pass an Act through. So that if an Act crippled them they might wait twenty years before they could get the Government to consider the grievance serious enough to decide upon giving sufficient time to the matter to have it altered. They should accept what they could get in the way of legislation, but use all their influence to so order matters that it should be possible to get the details of that legislation changed—to be under the influence of local bodies. And these bodies should not be distrusted. They might be bad to them to-day, but they would get wiser to-morrow, and when they got wiser they could carry out their new-found wisdom without waiting for Parliament to give time to confirm it. All their influence should be thrown into getting the securities put against the administration of those laws from the point of view of prejudice. In conclusion, he said his advice had been given as he thought that at this moment they must pull all together.

The Chairman, in responding, having referred to the compliment which had been paid them by the presence of their friend Lord Roberts, said that their difficulties must be surmounted by education. He meant the education that teaches us to be considerate for others. He referred to that education which teaches us that instead of giving little room we should give lots of room to that unruly animal the horse, and to do as Mr. Fletcher Moulton suggested, or rather, as he did not suggest, namely, to look behind you to see what dust you were making, and try to make a little less. It is in these matters that our education was going on, and he knew its beneficent effect was rapidly progressing, and he was certain it was owing to that that we might look for what he believed will very shortly be an improved state of feeling in the country as regards motoring. They must convince the public what the motor was and is going to be—to bring it home to their minds, if it had not been already brought home to them, that it was no longer a luxury of the rich, but was rapidly becoming a necessity of the

poor. In this great work of showing the public what a powerful factor the motor was going to be, it would be difficult to get an institution so capable and well fitted for the task as was the Motor Union—with its numerous branches and affiliated clubs throughout the country. It had the power, which no other institution possessed, of coming into touch with local needs, and of coming into touch with the people in the localities, and if, as he trusted it was, the education was going ahead fast, he thought it would be due to the Motor Union. He felt certain that all of them who were present would look back to that day and be proud of having had a part in these proceedings in early days, of having been pioneers in this great movement, and having done so much to raise the trade and the motor industry in this country to a level with and even higher than that of the rest of the world; and, further than that, that they would be proud of the part that they had taken in this great social revolution which, more than any measure that had ever been conceived by social reformers, would tend in the future to ease the burdens and alter the lives of the toiling masses who had so large a part in bringing prosperity to our country.

Mr. G. T. Langridge proposed the toast of "The Affiliated Clubs," which was responded to by Major E. R. Pardoe, Captain J. A. Cole, Mr. R. J. Smith, and Mr. R. A. Atkey, whilst the toast of "The Ministers of our Movement, the Roads, the Cars, and the Press," was very efficiently proposed by Lieut.-Col. R. E. Crompton, C.B., and responded to for "The Roads" by Mr. H. P. Mayburn (County Surveyor of Kent), "The Cars" by Mr. E. M. C.

✱ ✱

ONLY quite recently a splendid house-warming was made by Argylls, London, Limited, when a number of friends of Mr. Eustace Watson gathered together to wish him success in the new London undertaking. Last week the parent company, "Argyll Motors, Limited," held their Annual Dinner in the same room, at the Trocadero Restaurant, as the London branch. This annual function of the Argyll firm serves as a very pleasant reminder of the marvellous progress which has been made by those responsible for the building up of this extraordinary business.

Mr. W. A. Smith, who from the first has shown such confidence in the undertaking, has been well rewarded for his foresight, and in replying to the toast of "Automobilism," upon the occasion proposed by Mr. R. J. Smith, he was emphatic in regard to the wisdom of welcoming competition from the entire world. If they could not do better than their neighbours then they did not deserve the business. He thought that though we might at present be chasing foreign makers, it would not be long before they would have to chase us. Automobilism would bring about a regeneration of the public by introducing activity into every phase of life, particularly among pedestrians when moving about the streets and roads.

Mr. Alec Govan, in putting forward the toast of the "Argyll Representatives," as usual, kept the guests in continuous good humour by a string of stories of a piquant although appropriate character. As an example of the personal interest which the directors took in the Company's welfare, he drew attention to the fact that every member of the Board of the Argyll Company was then present at the gathering. They had helped by their work to build up part of the automobile industry to its present prosperous condition until he thought it was the envy of all other trades. At least he formed that opinion by one amongst many applications which he had received for employment from a man who had successfully managed five barges, three public houses, and a laundry, and who thought automobilism was a more promising field than any. He also mentioned the fact that the members of the Royal Commission on Motor Cars had visited the Olympia Exhibition on that very day, and whilst inspecting the Argyll stand expressed their astonishment at the enormous interests involved. Viscount Selby, the chairman of the Commission, was so impressed with the

Instone, and "The Press" by Mr. R. J. Mcreedy. Mr. Sidney Straker had charge of the important final toast, "The Chairman."

Automobile Mutual Protection Association.—At the meeting of the Council of the Association last week, Mr. E. Lisle in the chair, it was decided to pay ten guineas for affiliation with the Roads' Improvement Association, and to make a contribution of twenty-five guineas to the Legislative Fund of the Joint Committee of the A.C.G.B.I. and the Motor Union. Certain alleged infringements of patent matters were gone into and dealt with. Steps were authorised to obtain a length of several miles of main road for the purpose of conducting experiments with dustless materials. It was also determined to arrange for an examination of the Private Bills deposited for the next Parliamentary Session, and to take the necessary steps to oppose clauses likely to be detrimental to automobilism. In regard to the next General Election, it was decided not to ask Parliamentary candidates to pledge themselves with regard to motor car legislation, except that they should be asked to support the findings of the Royal Commission.

THE Society of Automobile Mechanic Drivers are holding a general meeting at 51, Brick Street, Piccadilly, on Monday next, December 4th, at 7.30 p.m. All mechanic drivers will be welcomed to the meeting, and cards of admission sent upon application to the Secretary.

✱ ✱

model to scale of the administrative building of the Company in Dumbartonshire, which formed the upper part of the stand of the Company's exhibit, that he said it was the biggest surprise he had had, and enabled him to grasp very vividly the importance of the industry and the resolution and enterprise of the men behind it. Mr. Govan, continuing, said that a big artistic building, however, did not necessarily mean good cars. It was what was behind that building. The directors and the management had, therefore, set themselves out to get the best of everything—workmen, tools, and materials—and to work at a minimum profit, relying on the quantity to pay for them. It was by their up-to-date machinery they were achieving their great success. Agents, he thought, might be compared with missionaries, as they were continually converting the man with money to the idea that he must have a car, and thus obtain health and unlimited pleasure, besides being the means of providing work to thousands of British artisans.

Amongst some interesting points disclosed at the gathering was the fact that the Company was established less than six years ago, and that for some time serious thoughts were entertained of relinquishing business, which at first was far from remunerative. The Board and management, however, stuck to their guns, and have had the satisfaction of seeing the Company emerge from the struggling stage and become a large and flourishing concern. The most significant development, however, was within the past twelve months since last Olympia Show, when soon after "Argyll Motors" was launched, the capital being largely over-subscribed, and the shares at the present moment standing in the open market at a substantial premium. The splendid new buildings which are now nearing completion at Alexandria will, it is hoped, be ready for occupation by the end of the year, and the works in full operation shortly after. The Company intend to devote the new works to the production of four-cylinder cars and commercial vehicles exclusively, the Bridgeton factories being retained for two-cylinder cars and for repairs, replacements, &c. At the present time over 1,000 cars are on order in the Company's books, representing more than half a million sterling, and the new factory will have its work cut out, up to at least the end of June next year, to carry out all the present orders for the supply of cars.

RACES, RECORDS, AND TRIALS.

statuette of Hermes inside it. The pedestal on which the Trophy is to be mounted will be 9 ins. in height, and is to be of enriched bronze, with seated figures representing Industry and Invention cast in full relief. This also is the work of a well known artist, Mr. Walter Gilbert, so that in all, the complete Trophy will be representative of the genius of three leading contemporary artists, while one of the finest works of the Italian Renaissance is at the same time reproduced. Mercury was the patron of many arts, particularly of working in metal, and, as the messenger of the gods, was also identified with speed. Hence, no doubt, the adoption of a statue of this deity for the Tourist Trophy. It will certainly be admitted that the Automobile Club—assisted by that indefatigable worker, Mr. Mervyn O'Gorman—has done its utmost that the Trophy shall be worthy of the occasion, and neither trouble nor expense have been spared. It is anticipated that the finished work will be ready to hand over to the winners towards the end of February.

Herkomer Cup, 1906.—The Bavarian Automobile Club have intimated that the trial for the Herkomer Cup next year will start from Frankfort-on-Maine. The route will be from that city to Munich, Vienna, and back to Munich, where it will finish. This announcement is not final, but indicates the trend of opinion.

Voiturette Competition.—The contest for voiturettes arranged by *L'Auto*, and of which we published details of the regulations in our issues of October 28th and November 4th, commenced on November 21st last at Suresnes, near Paris, and extended over six days, each day's run being to Gaillon and back. Twenty-two entries were received and thirteen actually weighed in and started, particulars of these being given in our table, together with their official numbers. On the first day the cars had a bad experience, snow being thick on the ground. Bad, however, as the roads were, some remarkably good performances resulted, the three De Dions, one driven by Lionel De Dion, being particularly noticeable, these getting through without losing a single mark, as did also one of the Lacoste cars (No. 16) and two of the Gregoires (Nos. 1 and 2). Two cars abandoned the contest, viz., a Lacoste (No. 22), and the Hugot (No. 14).

The second day the three De Dions again got through without a miss, followed in like fashion by the same two as the first day—the Vulpes and Nos. 17 and 22 Lacostes—all the eleven cars successfully covering the full course.

On the third day a little variation took place in the monotony of non-penalised runs, those with clean sheets being Cormier's De Dion, three Lacostes, two Gregoires and the Vulpes. The other two De Dions, having made a mistake in the time, were penalised for the amount in excess allowed under the rules, and thus spoil their otherwise splendid performances. The fourth day saw all the cars with no marks against them. The next day, the Gregoire car was heavily penalised through severe tyre troubles and delay, leaving only Cormier's De Dion and the Lacoste car with a clear run for the trial up to date. The sixth and last day of the regularity run was a break-up of all non-stops, through some miscreants who had evidently maliciously strewn the Paris-Mantes section of the road with huge bent nails, which played such havoc with the competitors' tyres that the whole question was placed before the judges for special consideration, and the afternoon run, it was determined should,

THE TOURIST TROPHY.—The Hermes of Giovanni di Bologna, at present in the Museo Nazionale at Florence, of which a golden replica, executed by Sydney March, will form the actual Tourist Trophy.

The Tourist Trophy "Trophy."—The actual Tourist Trophy which was won in the summer by the Arrol-Johnston Car Co., and is now gradually materialising, is going to be a very artistic affair. As our readers are aware, the Trophy itself consists of a replica in gold of the Hermes, by Giovanni di Bologna, in the Museo Nazionale at Florence, which is being made to the order of the Automobile Club by Mr. Sydney March, a well known sculptor, who has enjoyed the distinction of making busts of the King and Queen, the Prince and Princess of Wales, the late Pope, and Mr. Cecil Rhodes. The golden Hermes will be enclosed in a casket, of pierced damascene steel and silver work, designed by Mr. H. Wilson. The casket, which is 18 ins. high by 8 ins. square, can be opened so as to display the

under the circumstances, terminate at Mantes, as it was quite impossible for the competitors to hope to get back from there to Paris, except under equally distressing conditions as upon the outward journey. Prompt action was taken by those concerned in the trial, and a substantial reward offered for the discovery of the criminals who had so violated the laws of the highway. Probably special allowances will be made by the judges for this day's tyre mishaps. The concluding portion of the trial was on Monday, which was devoted to speed tests on the flat, on the hill, and to trials of starting and stopping efficiency.

The best time on the flat kilometre was made by Lionel De Dion of 1m. 40s. On the hill the Vulpes car was best in 4m. 5 $\frac{2}{5}$ s., and in the starting and stopping test over half a kilometre the Lacoste car (No. 16) was first with 57 $\frac{3}{5}$ s. In regard to the result of the reliability runs, the "Regularity Cup" goes to the De Dion Bouton team for their running over the 1,200 kilometres, the full distance of the trials, whilst it remains for the judges to decide the results of the whole trial, taking into consideration the very unpleasant episode of the cloud of nails which were strewn on the last day on the Paris-Mantes road.

Bogus Motoring Schools.—The sequel to the charge against George Stevenson, engineer, and H. McAllister, clerk, for conspiring to obtain money by false pretences from young men, who answered an advertisement inviting them to become pupils to learn motor driving and to be introduced to the motor industry, was enacted at the Clerkenwell Sessions on Friday of last week.

The judge—Mr. Loveland-Loveland, K.C.—after the jury had found the prisoners guilty, said the case was one of a cruel fraud on struggling men, and sentenced Stevenson to twelve months and McAllister to nine months' imprisonment.

Co-operation.—Messrs. Richard Melhuish, Limited, are amongst those old-established firms who, moving with the times, have thought it wise to take into partnership those associated actively with them throughout the business. The apportionment of the profits, beyond a certain amount, to the various work-people has been vastly appreciated and has brought about a remarkable discrimination in the conduct of the workmen, which is reflected in the admirable manner in which the firm's whole establishment is conducted. This is the first year in

which the new co-operative system has been in force, and we learn with very considerable gratification that the new arrangement has been of a most satisfactory nature to both sides, the first half-year's division of profits having shown extremely good results.

AT OLYMPIA.—One of the 10-12-h.p. Argyll Touring Cars, fitted with Side-entrance Body. This is the smallest of the numerous models made by this well-known firm, all of which were illustrated and described in our columns recently.

CORRESPONDENCE.

TOURIST TROPHY REGULATIONS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I am very pleased indeed to see Mr. C. Johnson, who initiated the Tourist Trophy Race, disagreeing with the policy which admits a steam car into this competition, and gives it a fifty per cent. advantage over the petrol car. It seems to me that the makers of steam cars might well say "Save us from our friends," when the Tourist Trophy Regulations widely advertise the fact that a steam car, to compete with a petrol car, has to be an abnormal consumer of petrol. Surely the steam car has some advantages which can be put against its petrol-consuming powers, and I certainly think that any competition in which the conditions vary for different competitors can only be misleading and unsatisfactory, and I agree with your correspondent in hoping that the rules will be altered so that it is a fair field and no favour for any competitor or type.

Yours truly,
S. F. EDGE.

Nov. 24th.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I take exception to the expression Mr. Claude Johnson uses in his letter to the JOURNAL last week—"admittedly inefficient"—directed, as it obviously is, at the White steam car. The White Steam Car Company deserve fairer play than this after their sportsmanlike entry in a competition which they knew they could not possibly win.

It is a matter of common knowledge that the White steam cars use more petrol per mile than some petrol cars of the same nominal horse-power, but they can burn the cheapest grade of petrol, and what they cost extra in fuel they save in the wear and tear of tyres owing to their lightness, even distribution of weight, and sweetness of running. After 8,000 miles experience, I firmly believe that the White steam car is not only the most silent and sweetest running car on the market, but the most reliable and the cheapest car to keep up. For a rival manufacturer to speak of it as "inefficient," seems to me, as it must to all other users of this delightful car, to argue a jealous fear of its real superiority becoming too widely known.

Yours truly,
G. C. ASHTON JONSON.

Pelham Crescent, S.W.
November 24th.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In your columns I notice a letter from a correspondent protesting against steam cars being allowed a greater quantity of fuel than petrol cars, and referring to the possibility of an "inefficient" steam car winning the Trophy.

Therein I think he does an injustice to those steam cars which use paraffin as fuel, such as the Turner-Miesse and the Serpollet.

I suggest that the use of paraffin and other cheap fuels should be encouraged, as otherwise, unless fresh sources of supply of petrol are discovered, the cost thereof is likely to be increased at no distant date as the demand for petrol increases largely, as increase it must.

I take it that it is not the quantity in gallons that concerns the private owner so much as the actual cost thereof. The Turner-Miesse cars use paraffin as fuel, which is roughly half the cost of petrol, and therefore I claim that if a Turner-Miesse used two gallons of paraffin to one gallon of petrol required by a petrol car, it would not be fair to refer to the steam car as "inefficient" (as the correspondent in question does), for the total cost of the fuel would be less for the steamer than for the petrol car.

There are great advantages in the use of paraffin quite apart from its cheapness—less danger from fire and explosion, it can be obtained everywhere, even (at a pinch) at a country farmhouse miles away from the nearest town, as I have been able to obtain it before now, &c.

Now the A.C.G.B.I. have gone so far, may I suggest they should go a step further the coming season, and in all competitions under their control (including speed contests and hill-climbs), permit steam cars to show what they can do alongside petrol cars of the same price. I am in a position to state with authority there is a vastly increased interest in steam cars at the present time, and their advocates will never rest contented until steam cars are given the opportunity to show what they can do alongside petrol cars in open competitions throughout the country.

The prospective owner of a motor wants to select the best car for his particular purpose. Let him be in a position to judge from the results of the competitions whether the steam cars fulfil the claims

put forward by their advocates. For my part, if given this opportunity, I will enter a Turner-Miesse in every possible competition if they are thrown open to steam cars.

Let the A.C.G.B.I. give the steam cars their opportunity for one season, and I venture to say the number of modern steamers on the road, such as the Turner-Miesse, White, Serpollet, and Stanley will increase by leaps and bounds.

Yours truly,
TURNER'S MOTOR MANUFACTURING COMPANY, LIMITED,
J. BURNS DUMBELL,
Managing Director.

Nov. 22nd.

SIX-CYLINDER versus FOUR-CYLINDER ENGINES.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I notice that Mr. Jarrott is under the impression, and I assume of course that he gains this by experience with the motor cars in which he is interested, that four cylinders are more economical in the consumption of petrol than six.

In view of the fact that it is undesirable that anyone in this country should be under any misconception as to the merits of six cylinders, even on the question of petrol consumption, I wrote to the Automobile Club to ask them if they would undertake an official test for this purpose over three or four hundred miles of road, and I find that they will do so. I was therefore making arrangements for a 40-h.p. 6-cylinder Napier to be tested in this way, and the results publicly announced.

In view, however, of Mr. Jarrott suggesting that he has found arguments in favour of the 4-cylinder *versus* the 6, I thought it would be fairer to suggest that instead of my running a 40-h.p. 6-cylinder Napier merely for a consumption trial, results of which I know would be very excellent, that it would be better that Mr. Jarrott should simultaneously, under the club auspices, and, if necessary, even drive himself, a latest 40-h.p. De Dietrich, such as he recently exhibited at Olympia, as I think it would be only fair that his latest model should be allowed to perform. I would run a latest 40-h.p. 6-cylinder Napier. The two cars could keep together, so that they would be both tested under identical road conditions, and thus set at rest (once and for all) this point.

There is just one point on the question of economy that Mr. Jarrott has overlooked, and that is to compare the tyre bill of his 4-cylinder 40-h.p. with the tyre bill of a 6-cylinder 40-h.p. The latter is very much easier on tyres.

As it may be that Mr. Jarrott will not have a finished 40-h.p. of his latest model available for such a purpose, I will be quite agreeable if chassis only are run, each weighted up with 10 cwt. of ballast.

Trusting Mr. Jarrott will accept this interesting test, failing which I will run a 6-cylinder Napier under the club auspices in the manner I have suggested.

Yours truly,
S. F. EDGE.

Nov. 24th.

Re NUMBER OF CYLINDERS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—The letter in your last issue in reference to the number of cylinders is exceedingly interesting, as showing how even such a generally well-informed manufacturer as your correspondent is, can overlook many points of advantage that the 6-cylinder engine gives to a motor car, and to the user of it.

It is, of course, pleasing to read from so eminent an authority that he agrees that there are a number of points in favour of the 6-cylinder engine, and he then very properly goes on to set out what he considers are the disadvantages; but I hope to show you clearly that these points which he refers to are the result of a slight lack of knowledge on the subject, and have nothing to do with the 6-cylinder principle.

Error No. 1.—He suggests that a fly-wheel of twice the weight required on a 6-cylinder car of the same horse-power is not a disadvantage, as the extra two cylinders would weigh as much as the heavier fly-wheel on the 4-cylinder car. Let us, for the purpose of argument, agree to this. He forgets, however, how much heavier all the shafts and other parts which have to take the wear and shock would have to be to take the greatly increased shock of the explosion of the 4-cylinder engine, plus the fly-wheel, twice the necessary weight. This would increase the whole weight of the car very greatly if equal wearing capabilities were expected from it that one would get from a similar horse-power 6-cylinder.

Error No. 2.—*Re* loss of wall heat, I think he has confused loss of wall heat with loss of power. If he would kindly work out what 18 per cent. loss in wall heat means, compared to its influence on loss of horse-power, he will find it so small as to be not worth considering. Obviously, if one only made an engine from the point of

view of reducing the loss through wall heat, one would simply have a single-cylinder engine of the greatest possible dimensions, but your correspondent is quite as well aware as I am that this would not be a practical vehicle, as the other parts of the car would have to be so abnormally heavy to stand this fearful shock that the car would not be a practical vehicle, and it is for this very reason that the 6-cylinder engine, owing to its extraordinary smooth turning motion, enables one to reduce weight in gears, transmission, and fly-wheel, and yet at the same time produce a car with which a guarantee as to freedom from mechanical repairs can be given, that it is impossible to obtain with a fewer number of cylinders.

Error No. 3.—In regard to petrol consumption, perhaps your correspondent would state what he considers would be the correct petrol consumption of the 40-h.p. 4-cylinder foreign cars which he sells, and I should then be pleased to run a 6-cylinder 40-h.p. Napier against his car for petrol consumption, and show him that even in petrol consumption a 6-cylinder 40-h.p. will consume less petrol than a 4-cylinder 40-h.p. foreign manufacture such as he supplies.

Error No. 4.—In regard to his suggestion that a 6-cylinder engine necessitates an abnormal wheel-base, this requires no answer on my part, I need only refer him to the published details of the foreign car in which he is interested, and he will there see that the wheel-base of his 40-h.p. car is given as 10 ft., and in the same information published he will see that the wheel-base of the 40-h.p. 6-cylinder Napier is 9 ft. 8 ins., 4 ins. shorter than his own car. Personally, I do not consider the wheel-base of his car is abnormal, but if he thinks it is then I would suggest him having his design altered to that which he thinks is correct. The Napier design I leave to the approval of those who purchase them, and who can see them at Olympia.

Error No. 5.—In regard to the question of silence and flexibility, it is of course obvious that to take two engines of a given h.p., the one that has six cylinders must obviously be quieter and more flexible than one that has a less number of cylinders, simply because each of the six can have a smaller explosive charge in it, just in the same way that a nine-inch gun makes more noise than a rifle per explosion.

Thanking him for the opportunity he has given me to correct evident fallacies that exist among well-informed manufacturers, and trusting that his factory arrangements will soon permit him to appreciate the merits of six cylinders as the public do.

Nov. 24th.

Yours truly,
S. F. EDGE.

A 6-Cyl. Thornycroft Car.—Six-cylinder cars continue to attract the attention of more and more automobile manufacturers, the celebrated Thornycroft the latest to adopt a model of this class is to be of 30-h.p., with $4\frac{1}{2}$ -in. bore, but the engine resembling, in general, the present 24-h.p. model. The car is of about 11 ft. 6 ins., and a track of less to say, it will have a "live-axle."

The "Austin" Touring Cars.—Particulars are now available concerning Mr. Herbert Austin is about to be built at large works near Birmingham that he has acquired for the purpose. Of the live-axle type, with propeller-shaft drive, the 15-20-h.p. model will have 870 mm. by 120 mm. tyres on the rear wheels, 870 mm. by 90 mm. front tyres, and the gear-box will provide three forward speeds with a direct drive on the third, whereas the 25-30-h.p. chassis is to have tyres of 920 mm. by 120 mm. and 910 mm. by 100 mm., and there will be four forward speeds. Both engines have four vertical cylinders, with low-tension magneto or high-tension battery ignition (or both on the larger car), while a sliding cam-

shaft permits the compression to be reduced for starting, and a forced-feed system of lubrication is employed. Water-cooled foot-brakes, internal hub brakes, ball-bearings for the entire transmission, and lever control from above the steering wheel are further features of both cars. The 15-20-h.p. engine has cylinders of 4 in. bore by 5 in. stroke, and on the larger model the bore is $4\frac{1}{2}$ in. with a 5 in. stroke.

The Coupe des Pyrenees Theft.—Much sympathy will be felt with Messrs. Jarrott and Letts in regard to the singular theft of which they have been the victims. As English agents for the De Dietrich firm they procured from the Baron de Türckheim, chairman of the De Dietrich Company, the loan of the Coupe des Pyrenees—a trophy which was won by a De Dietrich car in August last. The trophy, which is very artistic, representing the nude figure of Venus seated in her car (rendered appropriate to the occasion by the addition of a steering wheel) was about 2 ft. 6 in. long and nearly 2 ft. high. As visitors to the exhibition will recollect the trophy formed an attractive feature of Messrs. Jarrott and Letts' stall. During the first days of the exhibition Mr. Letts had the trophy removed each evening into the offices at Olympia, but subsequently he thought it would be safer to engage a night watchman. On Saturday morning, according to the night watchman, the trophy was safe enough at six o'clock. The night watchman left the stand for a few minutes when the usual cleaners arrived at that hour, and when he returned the trophy had disappeared. Considering its weight and size the thieves must have been expert, audacious, adroit and muscular. There was only one exit by which they could have effected their escape, and they appear to have vanished, "leaving not a rack behind." Since the disappearance of the trophy Messrs. Jarrott and Letts have offered a reward of £50 "with a view to its recovery."

The Pyrenees Cup, which disappeared in such a sensational manner from the stall of Messrs. Charles Jarrott and Letts, at Olympia last week. This Cup was won by a De Dietrich Car during the past season in connection with the arduous competition which took place through the Pyrenees and district

An Omen.—One night last week, a birth took place on the top of a Vanguard motor omnibus, and we are informed that both mother and child are now doing well. It requires no very expansive imagination to interpret this as an omen of universal future prosperity for the motor 'bus.

CONSIDERABLE interest has been created amongst motorists in America by the news that the Oldsmobile Company are bringing out a car having a twin-cylinder, two-stroke engine.

THE Congress, called in Paris, of the Automobile Clubs of Europe, to arrange, if possible, dates for the various leading motor racing events and tourist car competitions for 1906, has been fixed to take place on December 16th at the stand of *L'Auto* in the Paris Salon.

PERSONS in the Metropolis who desire to supply water (at a cost) for the use of motor vehicles, will, in future, have to take out a licence of 10s. per annum for permission to be allowed to do so, and will have to use water meters as well. It should be borne in mind that the sale of water for any purpose by consumers, unless licensed by the board or company who supplies them, is illegal.

A GOOD move has been made by a local paper, the *Kentish and Ashford News*, who are issuing from time to time a list of roads (from information supplied by the district surveyors), which are "up," that is to say, being re-metalled. If the local papers would go still further, and add to their list of roads that are "up," roads on which the police are "out," and where they are situated, they would still further incur the gratitude of automobilists.

IT is said that visitors to Switzerland find almost the only available meat to consist of mutton, and the situation is accordingly far from pleasing to many *gourmets* who like variety of diet. Our comic contemporary, *Das Schnauferl*, suggests that in future the Swiss authorities should give a little more liberty to automobilists, who would then run over other animals as well as sheep, and the restaurants would be able to provide the needed variety.

THE popularity of the motor 'bus, and the effective manner in which it is dealing with the London traffic, are beginning to produce their effect outside London, and one is pleased to see that Alderman Regester, in the Middlesex County Council, said at the recent meeting of that body that he doubted the advisability of constructing any more tramways when motor 'buses were so well able to deal with the traffic. Unfortunately, the Council was of another opinion, and passed new tramway schemes for north-west Middlesex. There is something mysterious—if, indeed, it is still mysterious—about this almost indecent haste to get down electric trams while there is yet time.

FOLLOWING up their show of high-class models of Fiat cars at Olympia, Fiat Motors, Limited, during the early part of this week indulged in a further exhibition entirely on their own account, at 37-38, Long Acre, where, in addition to the chassis and carriages shown at Olympia, where the restriction of space prevented any-

thing but single models being exhibited, on the various floors on the Fiat premises a grand variety of these cars were displayed to the stream of visitors who took advantage of the invitation of the company to see their latest models. Fiat X., the famous motor boat cruiser and racer, and Lancia's racing car were special attractions on the ground floor, Mr. Victor Miller and Mr. D'Arcy Baker dispensing hospitality whilst imparting information to their numerous guests.

COMMERCIAL POINTS.

Legros and Knowles, Limited.—The employees of Messrs. Legros and Knowles, Limited, the well known makers of the "Iris" car, held their first annual dinner at the Clarendon Hotel, Hammersmith, last week. Although it was a large and representative gathering, unfortunately, owing to their attendance being required at the Exhibition, the directors were unable to be present. Mr. J. E. Booth was in the chair, and proposed success to the firm in a short but characteristic speech. Mr. E. Codling replied on behalf of the directors. The toast of the "The Iris Car and the Iris Boat" was naturally honoured with great enthusiasm. After the dinner the whole of the gathering adjourned appropriately, per motor 'bus, to the Shepherd's Bush Empire, where the very pleasant gathering was brought to an interesting close.

THE Continental Tyre Company have issued their new price list, No. 10, for Continental motor tyres for the season 1906, which cancels all previous lists. List No. 10 includes all particulars of their new non-skid tyres, in addition to their round and square tread motor tyres, tyre accessories, &c. Owing to the large increase in the business of the company, they have been compelled to enlarge their premises in Clerkenwell Road, and have acquired the adjoining building, viz., 102, Clerkenwell Road. They are also opening a new depot in Manchester at 255, Deansgate. In Glasgow, again, they are removing to more commodious offices at Baltic Chambers, Wellington Street, where Mr. R. A. Whyte will be in charge.

The popularity of the Continental tyres can be appreciated from the fact that about 430 wheels were fitted with them at the Olympia Show, a far greater number than at last year's exhibition. Altogether 21 different makes of tyres, we learn, were represented at the Show.

THE continued headway being made by British-made tyres for heavy traction work is very remarkable. The most recent case in this respect is that of the Sirdar Rubber Company, Limited, who have just secured from the Star Omnibus Company a contract to the amount of £10,000 for their Royal Sirdar omnibus tyres. These are to be of the same type as those which have been running on the company's double-decked omnibuses in London during the past six months, the new ones being destined not only for replacements when necessary on these 'buses, but also for the additional motor 'buses which the Company are putting on during the ensuing twelve months, and of which they expect to have twenty-five on the roads by the end of February next. This contract is only one of several similar contracts which run over the next two years which the Sirdar Company have secured, and altogether their enterprise in taking over the big works at Bradford-on-Avon is already more than justified by the work which they have in hand.

A RECEPTION was given on the 24th instant by the sale staff of Messrs. Humber, Ltd., to their sales manager, Mr. J. W. Adams, in the Louis XVI. Room at the Trocadero Restaurant. Mr. E. F. Johnson, manager of Messrs. Humber's London depot, was chairman on this occasion, and performed the duty of proposing what proved to the great delight of everybody the only toast of the evening, viz., the health of Mr. Adams. The success of the Humber firm commercially is largely due to Mr. Adams' personal efforts and activity, and as he is extremely popular with the whole staff the proceedings were of a jovial and hilarious nature, the party subsequently adjourning to a popular place of amusement.

THE Scottish Motor Engineering Company, Limited, advise us that they have now fitted up a garage and two large shops in connection with their works at Granton Harbour, Edinburgh, which will be used exclusively for repairs of motor cars of any type. Qualified engineers and repairers will always be in attendance. Automobilists should note the address, as the works are situated on the main road from England to the north of Scotland.

Torquay Motor Omnibus Company, Limited.—At the annual meeting of this Company on Tuesday, it was decided to pay another annual dividend of 7½ per cent. upon a capital of £5,000. The year's receipts amounted to £5,455, and the gross profit was £1,462. The petroleum used as fuel cost £561, and lubricants £110. Renewal of tyres cost £391.

NEW COMPANIES REGISTERED.

Barnett's Motors (Limited).—Capital, £5,000 in £1 shares (3,000 preferred ordinary and 1,500 deferred ordinary). Object, to acquire a business carried on by H. H. Barnett at 128, Bristol Street, Birmingham. First directors, F. T. Murray and H. H. Barnett.

Leech Tyre Company (Limited).—Capital, £1,000 in £1 shares.

London and South Coast Motor Service (Limited), 68, Victoria Street, S.W.—Capital £100,000 in £5 shares (of which 6,666 are to be allotted in part payment of purchase price, and 13,334 offered to the public). Object, to provide a service of fast motor coaches between London and Brighton, Hastings, &c., and to take over the motor coach service now run by J. W. Cann between Folkestone and Hythe, and to extend the same to Dover and Lydd. First directors, W. H. Davis, J. P., F. C. A., T. Prior, C. Roberts, J. W. Palmer, and J. W. Cann, M.I.M.M.

New Revolution (Limited).—Capital £2,000 in £1 shares. Object, to acquire the business of cycle, motor cycle, and accessory manufacturers, carried on by W. C. Lloyd at Vauxhall Street, Birmingham.

NEW ISSUES.

The Motor 'Bus Company, Limited.—This company, formed with a capital of £305,000 divided into 300,000 ordinary shares of

£1 each, and 100,000 deferred shares of 1s. each, announce an issue of 150,000 ordinary shares at par. The company, it is stated in the prospectus, will work in harmony with the London Motor 'Bus Company and the London and District Motor 'Bus Company, Ltd., the Company seeking to specially serve districts running from Stamford Hill, Finsbury Park, Highgate, Leyton, Greenwich, Ilford and Barking to the City, besides cross routes in these districts, the routes being so arranged that the three companies do not overlap each other, or come into direct competition. The directors are Messrs. Esmond Caillard, Clarence Freeland, and Joseph H. Smith.

BANKRUPTCY COURT.

Re R. F. Dickerson.—A sitting was held last week for the public examination of Ralph Frederick Dickerson, described as of 84-86, Chancery Lane, E.C., journalist. The accounts showed liabilities £844, of which £644 was expected to rank, and available assets £31.

In answer to Mr. W. P. Bowyer, Assistant Receiver, the debtor stated that he was formerly in the mercantile marine, and afterwards in the motor trade. He has since been interested in three periodicals, known as *The Mobile Illustrated*, *The Motor Tourists' Guide*, and *The School Magazine*. On attaining his majority in October of last year he became entitled to £3,540, which he had since expended. He attributed his failure, among other causes, to the loss of £1,180 in connection with the periodicals mentioned, and to loss on the purchase and sale of motor cars. He had also been fined ten or twelve times, which had cost him, for furious driving, about £250 in fines and expenses.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

1219. 21st January, 1905. Improvements in Internal Combustion Engines. George E. Wright, 81, Gardengate Street, Barrow-in-Furness, and Herbert Parker, 87, Ashton Old Road, Manchester. The object of this invention is to provide convenient and effective means for reversing in internal combustion engines, and it consists in a valve-controlling mechanism comprising a second-motion shaft carrying two pairs of eccentrics, one pair of eccentrics being adapted to operate the inlet-valve or valves through the medium of an adjustable slotted link and a rocking shaft, and the other pair of eccentrics

being adapted to operate the exhaust valve or valves through the medium of similar mechanism. There are three figures. Fig. 2 is an end elevation of the twin-cylinder engine. The cycles of the two cylinders are coincident, and a common connecting-rod fitted to one crank-pin is employed. The pistons, *a*, have a forked connecting-rod connecting both pistons to the one crank pin; *e* is a second-motion shaft, driven by toothed gearing or otherwise from the crank shaft, and it carries two pairs of eccentrics, the first pair only being shown. The straps of the eccentrics are of similar construction, and are connected to eccentric rods pivoted at *r* to the slotted link, *f*. In the slot of this link works the block, *u*, pivoted to the rod, *v*, which is capable only of a vertical motion, being guided in the bracket, *w*. The

top of this rod, *v*, is pivoted to the bottom end of a small link, *x*, the upper end of which is pivoted to the rocking lever, *y*, which is keyed or rigidly attached to the rocking shaft, *z*. The shaft, *z*, carries levers, *2*, the lower ends of which act on the ends of the valve-rods, *3*. These rods, *3*, are formed integral with the exhaust valves, which are pressed open inwards by the levers, *2*, and closed by the action of the springs. The straps of the other eccentrics behind those shown are connected to eccentric rods pivoted to another slotted link. In the slot of this link works a block pivoted to a rod, also capable only of a vertical motion, being guided in the same bracket, *w*, which guides the rod, *v*. The top of this rod is pivoted to the bottom end of a small link, the upper end of which is pivoted to the rocking lever, *16*, which is keyed or rigidly attached to the shaft, *17*. The shaft, *17*, carries levers, *18* (only one being shown in the drawing), the lower ends of which act on valve rods, *19*. These rods are formed integral with the admission valves. These valves are pressed open inwards by the levers, *18*, and are closed by the action of springs. The blocks, *u*, can occupy different positions within the slotted links if these links are moved to the right or left. Any suitable mechanism can be used for actuating the slotted links, so as to alter the positions of the blocks within the links. When either block is at one end of the slot it is almost wholly under the influence of one eccentric and when it is at the other end of the slot it is almost wholly under the influence of the other eccentric. One eccentric is used (both in the case of the admission valve mechanism and in the case of the exhaust valve mechanism) when the engine is rotating in the usual direction, and the other when the engine is going in the reverse direction. By linking up, that is, by putting the blocks, *u*, in an intermediate position between the two end positions the power and fuel consumption of the engine can be reduced by limiting the extent of opening (both as regards distance and as regards time) of the valves.—November 8th, 1905.

29655. 31st December, 1904. Improvements in or connected with Buffer Devices for Vehicle Springs. George Johnston, c/o Messrs. Johnson and Co., McPhail Street, Bridgeton, Glasgow, N.B. This invention has for its object to provide a simple and

effective device for supporting a pneumatic buffer between the springs and frames of a vehicle, the device at the same time forming an anchor for the end of the spring. There are two figures. Fig. 1 is a longitudinal section. To the frame, *A* (or other suitable part of the vehicle) is fixed a casing, *B*, formed in two parts of trough-like section arranged one beneath the other, hinged together laterally at one end, *C*, and open at the other, the open end of the lower part of the casing working on a pin, *F*, depending from the frame and having in its lower end a collar, *J*, to limit the possible descent of this part of the casing. The two parts are so shaped as to form what may be termed a jaw, within which is placed a buffer preferably as shown in the form of a pneumatic cushion, *D*, but which may be of any suitable elastic material. Upon the under side of the lower part of the casing a lug, *E*, is formed, and to this lug the end of the vehicle spring, *G* (which is of leaf form, and is carried upon the axle as usual, part of the spring only being shown), is directly connected by a pin, *H*, passing through openings in the forked end of the spring and in the lug, *E*. A simple and effective buffer device is thus provided to absorb those shocks which, for example, occur when a vehicle is travelling over cobble stones, and which are too rapid to affect the springs.—November 5th, 1905.

PASSING EVENTS.

All Together!

THERE can be practically no doubt that we are at last not very far off a General Election. It may be delayed for a short time, but it is almost as certain as anything can be, excepting rates and taxes, that early in the new year will see the country in the turmoil of electing candidates for another Parliament. When the election takes place, owners of motor cars will be in universal request. If a single car owner in the country does not receive pressing invitations to place his car at the disposal of one or other of the candidates for his constituency, or even for other constituencies when dates permit of it, his case will be decidedly exceptional. Automobile owners will then have their chance. Let us trust they will use it wisely and well, and, as we have repeatedly urged in the past, absolutely refrain under any circumstances from assisting any candidate by the loan of a car who does not pledge himself to promote the interests of the movement by undertaking to support sensible and progressive legislation. There is something ludicrous in automobilists (as has often occurred in the past) finding they have lent their cars for electioneering purposes to support a candidate, who, as soon as he has got into Parliament, has done all he can to cripple and impede the automobile movement. It is accordingly with much satisfaction that we produce below the letter which Sir Alfred Harmsworth has written to the Press on the subject:—

"In reply to your request for the loan of my motor cars during the forthcoming election, I regret that until I have a definite under-

taking that you will support reasonable amendments to the present unjust laws in regard to these vehicles, I do not feel disposed to send to distant parts of England valuable cars, which I quite recognise are essential to the success of the forthcoming contests. I do not take this course without reason. Formerly I was in the habit of lending my automobiles to members of our party without any question.

"As a rule, the rough and tumble of an election seriously injures a motor car, but I am sure that all enthusiastic Unionists are willing to take that risk. In the past, however, I have had a valuable car returned to me badly damaged, and I was not pleased to find that the Member of Parliament who was assisted in gaining his seat by means of the vehicle in question, at once supported the legislation that has done so much injury to an industry that should be the means of finding work for at least as many of our mechanics as are employed therein in France.

"I would repeat that unless, therefore, you are prepared to give me your assurance that you will support reasonable legislation, on lines which I will suggest, I regret that I must reluctantly decline to despatch my vehicles to your help."

Let the Automobile take Precedence.

SIR ALFRED HARMSWORTH'S letter puts the case in a nutshell. There are ardent politicians, no doubt, who may feel some qualms about making terms with a party candidate, but if they are ardent automobilists, we would urge them to let the ardour of their politics, at any rate for this occasion, take the second place as compared with the ardour of their automobilism. After Sir Alfred Harmsworth's clear enunciation of his attitude they need have few misgivings. He is an ardent politician if ever there was one. The papers which he controls are systematically and vigorously conducted in a particular political interest, but he recognises that a critical situation has arrived in the history of the motor car movement, and all the power that automobilists can bring to bear on its behalf should be employed. His power is considerable. He is the owner of a fleet of motor cars large enough to set up a moderate dealer in practice. He has had experience, as will be perceived from his letter, of lending them at election times in the past, and he has evidently come to his decision after mature reflection on the results of his past experiences. After his example, no car owner in the country should have any hesitation in putting automobilism first and other politics second.

A Power to be Reckoned With.

As a matter of fact, if automobilists hold together stoutly and conscientiously, there will be no need for anybody to sacrifice his political convictions. If each candidate is assured, no matter in which political interest he may be offering himself, that if he gives the necessary assurances in regard to automobile legislation he will have a phalanx of motor cars at his disposal, while that if he refuses them he will have to rely on his old friend the horse and its congeners—the pony, donkey and mule—to convey his supporters to the poll, he will give the required assurances without hesitation. Few, indeed, will be the candidates who will refuse them. All the bye-elections which have taken place during the past few years have shown over and over again that in all elections at all likely to be close ones, the assistance of an adequate number of motor cars decides the contest. It must be remembered that in most recent elections there have been motor cars on both sides, though there have as a rule been more on the side of the winner than on the side of the loser. We ask candidates to think what chance they will have if all the motor cars available are on one side and none on the

other. They will have no chance at all, and they will know it, and whether they are Conservatives or Liberals, will give the required pledges. Every automobilist therefore, however strong his political convictions, may without hesitation determine to adopt the line that Sir Alfred Harmsworth recommends. If they all hold together the vast bulk of Parliamentary candidates will surrender at discretion, and the effect on the balance of political parties may possibly be inappreciable. But the future of the motor car movement will be assured.

♦ ♦ ♦

{Don't Nail His Ear to the Pump.

WE have never been struck by the impartiality of the King's Bench judges in cases in which the motor car has been concerned, and we must certainly say that we are not impressed with the judicial fairness of the remarks made by Mr. Justice Grantham, at the recent Kent Assizes, in passing judgment on Charles Guillemard, who, as our readers will remember, some time ago took a pot-shot with a rook-rifle at some passing automobilists, alleging, when asked why he fired, that "they go so fast they run over children." The defendant, Guillemard, had been committed for trial at the Assizes, and when he came before the Judge, at the instance of his counsel, he pleaded guilty to a common assault—the common assault consisting in discharging a gun "in immediate proximity to the motor car." This plea was accepted, and the other one of attempting to wound, or whatever it was, was allowed to drop, although it was proved in evidence that the bullet from the rook-rifle, which the defendant said was out of order, passed quite close to the head of a lady who was seated in the car. Mr. Justice Grantham, in giving judgment on the accused, spun forth a series of observations, which, if they had been attributed to a judge in one of the admired works of the late Lewis Carroll, would have undoubtedly been regarded as a masterpiece of humour. "He had read the evidence which was very conflicting, but there was a preponderance in the accused's favour" (which leaves it quite uncertain whether what preponderated in the accused's favour was the evidence or the conflictingness of it). "At the same time the prisoner had done a dangerous thing, and it was right that the case should be brought forward, in order that others should be warned from doing harm in that way." (But the charge of doing the dangerous thing has been withdrawn—there is no danger in firing a gun near a motor car, if you do not point it at the occupants.) "There was a great feeling in the country," went on the Judge, "with regard to motor cars, particularly in country districts, and there was some foundation for it. It was a wicked thing for motor cars to go the pace that some of them did, owing to children playing about the country roads. The only marvel was that children were not killed every day in the week. But *people must not shoot at motorists*, and although the accused might have fired in the air, he might have done serious injury or even something worse. If motor car drivers went too fast, they must be punished by law, but people must not use a gun on them." And then, *pour encourager les autres*, he dealt with the accused under the First Offenders Act; and he was bound over and liberated. No, people must not shoot at motorists, though if they do so, and explain that they only discharged a gun in "immediate proximity" to a motor car, and come before Mr. Justice Grantham, they will to all intents and purposes be let off!

A Judicial Scandal?

Now we would plainly ask the question: Is this or is it not a judicial scandal? Here is a man charged with committing a serious offence. He is brought before the magistrates, who commit him for trial at the Assizes. And then the Judge at the Assizes finally sentences him, under the circumstances described above, and under the First Offenders' Act—to be let off. Does anyone suppose that had the accused fired his rook-rifle in such immediate proximity to people driving in a horse carriage he would have been let off like this? Judges are supposed to administer the law without prejudice and without favour. Are Mr. Justice Grantham's remarks likely to encourage dangerous assaults on automobilists or are they not? Here was a man accused and proved to have fired a gun at the occupants of a car. Instead of reading him a lecture on the heinousness of his offence, the judge launches forth into a diatribe against the wickedness of motorists. Suppose, in the days of the old agrarian agitation, an Irish countryman had been found discharging a gun "in immediate proximity to" a landlord, what would have been said if the judge before whom he was tried delivered a lecture on the wicked ways of landlords, and commented on the excessive rent they extracted from their unfortunate tenants? We again ask: Do Mr. Justice Grantham's remarks amount to a judicial scandal or do they not?

Royal Commission on Motor Cars.—On Wednesday, last week, at the 25th, and at the following sittings of the Commission, further witnesses have been examined as follows:—Earl Russell, Mr. Cozens-Hardy, on behalf of the Automobile Club; Mr. Ross, chief engineer of the Great Northern Railway; Mr. Inglis, general manager of the Great Western, on behalf of the Railway Companies' Association; Dr. Bruce Porter and Mr. Lockwood, F.R.C.S., representing the Association of Medical Men using motor cars; Miss S. S. Bennet, on behalf of the Highways Protection League; Mr. J. Ogden Hardicker, on behalf of the Urban District Councils' Association; Mr. E. B. Newton, borough surveyor of Paddington; and Mr. Norman Scorgie, borough surveyor of Hackney, representing the Metropolitan Borough Councils; Mr. J. Lulham Pound, on behalf of the London Omnibus Owners' Federation; Mr. G. L. Gomme, clerk to the London County Council; Mr. D. A. Matheson, chief engineer of the Caledonian Railway; Mr. G. F. L. Foulger, on behalf of the Gas Light and Coke Company; Mr. W. B. Mason, land agent, Windsor; Mr. J. A. Steel, on behalf of the Highways Protection League; and Mr. W. W. Marks, Clerk of the Peace for the County of Bedfordshire.

The Commission, which has sat on 27 days and heard 110 witnesses since October 16th, has now adjourned until after Christmas. The Commissioners do not propose to take any further evidence before proceeding to consider their report.

Appeals.—We have received from the Motor Union some interesting particulars of appeals to Quarter Sessions in the case of convictions of automobilists. Since January, 1904, when the new Act came into force, there have altogether been 77 motor car appeals to Quarter Sessions. Of these 30 were successful, 37 were unsuccessful. In 7 cases the convictions were upheld,

but the penalties inflicted reduced—which 7 cases may accordingly be regarded as modified successes—and of the remaining 3 cases 1 failed on a technical objection, 1 was abandoned, and 1 was adjourned. Considering the constitution of Quarter Sessional Courts, this high proportion of successful appeals must be regarded as very encouraging. The Motor Union desires to see a modification introduced into the law which shall give the right of appeal in all cases of conviction. It is to be hoped that as far as Scotland is concerned, at any rate, this proposal may ultimately find its place on the Statute Book, as at present it is impossible to make an appeal in Scotland unless the penalty imposed in the first instance has amounted to £10 or more.

A Contrast in Police Regulations and Methods.—

The proprietors and builders of motor omnibuses cannot fail thankfully to recognise the extreme courtesy displayed by the Commissioner of Police of the Metropolis in the manner in which he has promulgated the regulations for obtaining licences for these vehicles, which we reproduce elsewhere. He has sent round to all the leading manufacturers a copy of the draft regulations asking for their remarks in reference to them, pointing out that they will not be required to be observed in the case of vehicles already built, or such as are so far advanced as to render their alteration impracticable, and asking what number of vehicles the particular manufacturers happen to have in this condition, so that they may be able to make exceptions to them. The Commissioner states that he desires to make the regulations, with the assistance of those to whom the draft copy was sent, of such a kind as to ensure the introduction of vehicles of a type suitable alike to the public and their proprietors, and that they will not require alteration for many years. It is most satisfactory to find so important an official adopting this courteous and conciliatory tone, and it is unquestionably of the happiest augury for the future of the motor 'bus and the movement generally.

A SOMEWHAT different spirit is, according to the statements which have appeared in the Press, being displayed by the City Police, who, if accounts are true, propose to limit the number of motor 'buses allowed to ply through the City, though they have not decided exactly what number they will allow. This decision has been taken in reference to the determination of the London Road Car Company, who have commenced a new motor 'bus service between Putney and Burdett Road, at Mile End, the total length of which is 10 miles. The double journey, 20 miles, is covered by the motor omnibuses in 2 hours and 10 minutes, horsed omnibuses taking at least 4 hours to accomplish it. The City Police allege that the probability of breakdowns interfering with the general traffic is the reason they propose to limit the number of motor omnibuses. One cannot help regarding this attitude as unnecessarily cautious. The number of breakdowns in motor omnibuses are relatively insignificant, and against them should be placed, on the credit side of the account, the much smaller extent to which the motor 'bus when running normally interferes with ordinary traffic, and the enormous acceleration of traffic which will ensue when *all* the omnibuses are mechanically driven.

HIGH-TENSION MAGNETO IGNITION.—PART XVIII.

THE GIANOLI SYSTEM.

(Concluded from page 1474.)

it is connected to the feeder brush, D^3 , which leads it to a brass ring provided with a projecting quadrant, or arm, D^4 . As the distributor revolves, this arm, D^4 , comes opposite to each of the distributor "brushes," D^5 , and the current is thus switched on to each ignition plug in turn. The special feature about this distributor is that the "brushes," D^5 , do not touch the distributor quadrant, D^4 , and the electricity has, consequently, to jump across in the form of a spark. The gap is, of course, very small, and not being surrounded by compressed gas, as are the ignition plugs in the cylinder, the extra spark is of comparatively small account. The advantages claimed for this system are that it does away with the friction of rubbing contacts and the consequent formation of fine metallic dust, and which is liable to cause trouble. Against this must be set the necessity for more accurate fitting, but this fact has been fully realised by the manufacturers, who have provided a carefully made and substantial fastening for the purpose. A safety-spark-gap, D^6 , is provided on the distributor for the protection of the secondary windings in the event of a breakage occurring in one of the wires to the plugs.

Timing the Ignition.

The system of hand "timing" fitted on this magneto is particularly simple, but we have not seen it adopted hitherto, although the system of rocking the entire magneto about the armature has already been introduced. With magnets of the horse-shoe type, however, this latter method would have many objections, and in any case it would be more costly to arrange than the system of moving separate pole-pieces, as is done in the Gianoli magneto. These adjustable pole-pieces, and the manner in which they are fitted, have already been described. Their movement is accomplished by the "timing" lever, K , which is attached directly to the bearing plate, M^1 .

Rocking these pole-pieces is equivalent to tilting the magnets themselves, and the instant at which the armature current is sufficiently powerful to operate, the contact-breaker is advanced or retarded accordingly. The high-tension distributor is not necessarily coupled to the magneto timing-lever, K , because the distributor quadrant is made sufficiently wide to ensure that it shall always be opposite to the correct "brush" for all positions throughout the timing range.

FIG. 11.—The Gianoli High-Tension Magneto.—View of the Coil-box which is specially wired to enable either the Magneto or the Battery to be used with the same ignition plugs. The switch is on the side of the box. The induction coil itself is, of course, only used with the battery ignition.

The High-Tension Distributor and its Connections.

In the Gianoli system the high-tension distributor is entirely separate from the magneto, but in order to connect it with the high-tension coil on the armature it is obviously necessary to have some form of "brush gear" for collecting the electricity from the revolving armature on to the stationary wire leading to the distributor. This, however, has been very simply arranged for by means of a spring contact, D^2 , which presses against the end of the rod, D^1 , as the armature revolves. The actual end of the secondary winding is, it will be remembered, coiled up on a rubber pad and it is against this that the inner end of the rod, D^1 , makes contact.

From the contact, D^2 —which is mounted on a neat ebonite screw fitting—the high-tension current passes along a wire to the separate distributor, which may be mounted on any suitable "half-speed" shaft. Here

FIG. 12.—The Gianoli High-Tension Magneto.—Detailed views of the Switch which forms such an important feature of the battery box illustrated in Fig. 11. This is, in reality, two switches, one half being low-tension, and the other half high-tension.

FIG. 13.—The Gianoli High-Tension Magneto.—Diagram of the connections inside the Coil-box showing how the two systems are isolated from one another. On the right are diagrams showing the three "positions" of the switch, which thus form a key to the other connections.

Some mention of the effect which the contact-breaker has in automatically timing the ignition has already been made. This is a matter, however, in which there are several counteracting influences at work, and at present there is insufficient data available to make it possible for us to give any very definite information on the subject. In Fig. 9, however, we give a diagram, based on assumed data, which illustrates the general principle of this action. Two curves, *a*, of current intensity are drawn on the same base line ($0^\circ-180^\circ$), which represents one half revolution of the armature. The higher curve, which represents an engine speed of 1,500 revs. per min., is, at all points, above the other curve, which represents an engine speed of 400 revs. per min.; it follows, therefore, that it will reach the line, *b*, sooner. The line, *b*, represents—as it does in Fig. 7—the instant at which the contact-breaker comes into action, and the distance between the points, *c*, and *c'*, therefore represents the amount (in degrees) by which the ignition is automatically advanced, when the engine speed changes from 400 to 1,500 revs. per min. It will be remembered, however, that at 1,500 revs. per min. the line, *b*, takes up some higher position, *b'*, on account of magnetic lag, and thus the automatic advance, *c*, *c'*, is counteracted by the amount, *c'*, *c''*. The lag in the armature-current itself would also tend to still further curtail this effect, but at present no data is available to enable us to give relative values to these different influences.

We understand, however, that there is a considerable amount of effective automatic timing in practice.

The Internal Electrical Connections.

The winding of the armature is shown in Fig. 10, and this diagram enables the system to be compared with the other magneto systems which we have previously described.

The only point to be specially noticed is that the high-tension coil is connected to the live end of

the primary winding instead of being earthed directly to the core. The primary coil is, therefore, included in the secondary circuit at the time the spark takes place, although it is independent of the secondary when the contact-breaker is closed.

The Battery Circuit and the External Connections.

It is not always a simple matter to install battery ignition as an auxiliary to a high-tension magneto—if both systems have to use the same ignition-plugs—unless the magneto system, as a whole, has been designed in the first instance for such use.

The manufacturers of the Gianoli magneto have therefore constructed an induction coil for use with the accumulators, and have enclosed it in a special box, which contains all the necessary terminals and interconnections to enable the battery to be easily installed and instantly brought into use, by means of the switch, when required. The

terminals in the box (Fig. 11) are all labelled in such a way that any motorist could easily make the necessary

FIG. 14.—The Gianoli High-Tension Magneto.—Diagram of external wiring showing the connections necessary when installing the system in a car.

connections, especially by the aid of the diagram in Fig. 14, which shows the complete scheme of wiring necessary for installing both systems. The internal connections of the coil-box are shown diagrammatically in Fig. 13, and this diagram is particularly interesting, because it illustrates the manner in which the two systems are isolated from one another.

The principal obstacle in the way of making a simple combination of high-tension magneto and battery ignition is that the secondary coil of one system "short-circuits" the ignition plugs whilst the other system is in use. A high-tension switch is, therefore, essential in systems which have two independent secondary windings connected to the same ignition plugs.

A low-tension switch is, of course, required in any case, in order to change over from one to the other of the two primary circuits. In the Gianoli system both switches are contained in the same case, and there is thus no difficulty in operating them simultaneously. The upper half of the switch (Fig. 12) is confined to the low-tension connections, and the lower half to the high-tension wires.

On the right-hand side of Fig. 13 the three "positions" of the switch are shown separately, and these, taken in conjunction with the rest of the diagram, render the connections self explanatory. The following summary of the functions which the switch performs is also given, however, because it is especially useful as showing the essential points to be provided for in an installation of this kind.

Battery On:—*Low Tension*: accumulator circuit closed, and magneto primary winding "earthed." *High Tension*: secondary winding of battery coil connected to distributor, and connection between distributor and magneto secondary winding broken.

Stop:—*Low Tension*: magneto primary winding "earthed," and battery circuit broken. *High Tension*: both circuits to distributor broken.

Magneto On:—*Low Tension*: battery circuit broken, and magneto primary circuit to "earth" broken. *High Tension*: magneto secondary connected to distributor, and the battery-coil secondary-circuit to distributor broken.

Table of Reference Letters for the Gianoli High-Tension Magneto System.

A Armature core.	D Secondary winding.	F ¹ "Live end of F.	N ² Contact-maker for battery circuit.
A ¹ Side plates of A.	D ² Spindle in contact with live end of D.	F ² Condenser case.	N ² Cam operating N ² .

Fire Brigade Cars.—The speed with which the chiefs of fire brigades can reach the scene of any conflagration by means of the motor cars which are now gradually being introduced for this purpose, enables them, in most cases, to reach the fire in time to grasp the best method of employing the engines for the subduing of the flames by the time that the engines themselves arrive on the scene. With the ordinary fire engine or a motor fire engine no difficulty occurs in rapidly clearing a way owing to the prominence of the vehicle, crowned by the firemen in helmets, and the well known cry of the firemen. With the official motor car, however, a very different state of affairs occurs, as, owing to the lowness of the seats of the car, the fact that it is an official fire brigade car is not instantly realised, in spite of the shouting of the occupants, and consequently delay occurs in many cases before traffic is held up or drawn aside. An instance of this character during the week brought home to us the desirability of some measure being adopted by the brigade whereby the approach of the fire brigade official car would be instantly recognised. We would suggest that a twelve or fourteen-inch gong, fixed in front, should be employed, similar to those in use in America and in certain Continental cities. It would be a very distinctive and penetrating warning, and should prove most effective in its results. We would further urge that, in the event of the suggestion being adopted, steps should be taken to render it illegal for the real boulder cyclist to adopt the same pattern (and size) gong, in similar fashion to the annexation by a certain type of the cycling fraternity of both the shrill and the deep voiced motor horn.

Thames Regulations for Motor Boats.—The Society of Manufacturers and Traders have decided to address a communication to the Board of Trade in reference to the proposed new bye-laws for petrol launches on the Thames, which has been approved by the Thames Conservators. There are many features of the bye-laws likely to prove troublesome to motor boat owners and the Motor Manufacturers and Traders are accordingly petitioning the Board of Trade to receive a deputation, so that before the regulations are finally passed the points can be discussed verbally.

Hurley Burly.—The effect of the movement in favour of constructing special roads for the use of automobilists has already produced a deadly result. It has once more brought up and into the Press the dreaded Vicar of Hurley. He is certain "that unless ere long motor cars are entirely abolished from public metalled roads on which horse-drawn carriages and pedestrians travel, and are relegated to tracks of their own, there will be a serious rising of the people in this country. Life is already nearly unbearable, and the nuisance gets monthly worse and worse. Most of the motorists are absolutely selfish. The nuisance is bad enough in towns, but it is far worse in the country." That was what we were afraid of. As soon as we noted that the project for separate motor roads was being advocated we at once recognised that it was certain to be seized upon with avidity by all the antimotor-monomaniacs in the country.

THE NEW ARROL-JOHNSTON PETROL CARS.—PART IV.

be used with safety, and the live-axle is attached to the frame by side radius-rods as well as by a central torque-rod.

The Change-Speed-Gear.

Figs. 17 and 18 are illustrations of the gear-box for the 12-15-h.p. car, the former showing it from the right-hand side—with the upper half taken off and the propeller-shaft lying in front—and the latter giving vertical and horizontal sections through it. Quite a short shaft

Fig. 17.—View of the Arrol-Johnston Gear-box, as fitted to their 12-15-h.p. Touring Cars. On the right is the upper half, which receives the Operating Sleeve, and beneath is the Propeller-shaft.

The Transmission Gear.

CONCERNING the main clutch, no very full details are necessary, since it is of the already well-known "Hele-Shaw" type, arranged inside the hub of the fly-wheel. The discs, of which there are a considerable number, are corrugated, and are normally pressed up together by three easily adjusted springs; the discs run in oil, and rely upon small spring blades to separate them when the pressure of the main springs is released by depressing the clutch-pedal. Owing to the small size of the clutch, it is possible to so shape the arms of the fly-wheel that they act as effective fan-blades for drawing air, past the engine, through the radiator.

It is the change-speed-gear, the universal-joints on the propeller-shaft, the spring-drive device, and the construction of the live-axle that therefore require our chief attention, and it will be found that each of these parts have some very decided features of interest. For convenience, each will now be considered in turn, with the assistance of the photographs and line-drawings from which we have prepared the necessary illustrations. But little need be said in advance about the positions which they occupy relatively to one another on the chassis, because we have already given drawings of the complete chassis. Between the clutch and the gear-box, a flexible coupling is introduced in order to relieve the shafts of all lateral strains that might otherwise result from the independent fixing of the engine and the gear-box direct to the side-members of the pressed-steel frame. Gear-boxes of somewhat different design are employed upon the two models, but in both cases there are only three points of support provided—two arms on one side and a single arm on the other side—and both gear-boxes have roller-bearings for their shafts. Similarly it may again be pointed out that the 24-30-h.p. chassis has an additional spring, placed transversely, at the back, whereas only the usual semi-elliptics are employed on the 12-15-h.p. car. On both, however, the suspension is such as to permit solid rubber tyres to

Fig. 18.—Vertical and horizontal sections, showing the construction of the 12-15-h.p. Arrol-Johnston Change-speed-gear.

Fig. 19.—The Change-speed-gear of the 24-30-h.p. Arrol-Johnston Car.
View of the Box from above, with the upper half removed.

jecting outwardly. The forks lie
at right angles to one another,
and are connected together by the

cage-fitting, H^3 , which is made in two parts and has socket-bearings for all four pins. Around the entire joint is an aluminium-casing, H^4 (shown intact in Fig. 20, but partly cut away in Fig. 18), which is fixed to the shaft, H , and is rendered oil-tight by a leather stocking (not shown) fitted between it and the propeller-shaft, H^2 .

The gear-wheels all run in oil inside the gear-box, but special provision is made for supplying the bearings. For this purpose, the main casings have passages bored out for the reception of cotton wicks, and these wicks, which draw up the oil by capillary attraction, feed it to each roller-bearing.

For the 24-30-h.p. car, the change-speed gear (illustrated in Figs. 19 and 20) is in the main similar, and consequently the foregoing description is to a great extent applicable, especially as all parts which correspond exactly with those of the 12-15-h.p. gear-box have been given the same reference letters in our illustrations. The chief difference lies in the method adopted for operating the various "speeds," and in the consequent adoption of two sliding intermediate spur-wheels (K^5 and K^6) for the "reversing" gear. Instead of there being three

sliding bars with one engaging arm, as in the previous case, there are two tubes (K^2 and K^3), each of which has its own engaging arm (K and K^1), while both the arms, K and K^1 , have their own concentric sleeves, which pass through to the double-slotted quadrant, and are alternately "caught up" by the hand-lever. The tube, K^2 , controls the wheel, K^6 —i.e., the third and fourth speeds—and the other tube, K^3 , not only operates the wheels, H^4 and K^5 , for giving the first and second speeds, but also controls the intermediate pinions, K^3 and K^4 .

This last-mentioned function is performed with the aid of a spring, K^7 , for the spring tends to slide the intermediate pinions into their inoperative position and the same fork that controls the wheels, H^4 and H^5 , can act in opposition to the spring, through the agency of the lever, K^4 . In this way, the tube, K^3 —when pushed rearward as far as it will go—brings the wheel, H^4 , into mesh with the wheel, K^5 , and also causes the wheel, K^6 , to slide into gear with the wheel, G^4 . A safety catch prevents the hand-lever from being moved into its reverse position by mistake.

(To be continued.)

ON Thursday evening last Mr. Filson Young read an entertaining paper before the Automobile Club entitled "Morals from the Olympia Exhibition." Among many amusing and distinctly original views which Mr. Young put forward, the principal was that the Automobile Exhibition should be conducted philanthropically by the Automobile Club, and organised on lines, not for enabling manufacturers and dealers to transact business, but to provide useful instruction for the young idea in the principles of motor car manufacture—an arrangement which would doubtless be highly convenient and useful for the compilers of books on automobilism. The discussion which followed was distinctly lively, the manufacturers who took part in it being not generally in favour of this method of organising an exhibition, which would, needless to say, be a form of public instruction for which they would have to pay the costs.

THE Automobile Exhibition which we announced a short time ago was to be organised by the Brighton, Hove and District Automobile Association at the Royal Pavilion, Dome-Exchange, is now announced to take place from January 15th to 20th, about one month earlier than was originally anticipated. This Association has already doubled its membership during the past two months, and as a result of the forthcoming Exhibition, it is hoped to further enrol a large number of the thousand or more motor car owners who reside in the district.

RECENTLY we announced the arrival in England of Mr. Alexander Winton, chairman of the Winton Motor Carriage Company, of America, and we gave a few interesting points in connection with Mr. Winton's remarkable career and success in the American motor industry, as imparted by himself at a pleasant little function at the Company's London premises, given to welcome Mr. Winton upon his arrival in this city. It was understood that a second object of Mr. Winton's visit to Europe was that in addition to visiting the Olympia Show he might attend the Paris Salon. A third object is now apparent in the fact that the forthcoming marriage of Mr. Winton is announced to take

place on December 12th, to Miss La Belle McGlashan, of Paisley, Scotland.

It does not in the least matter what excesses you commit—provided you are a horse. They will be either taken no notice of at all in the general Press, or if circumstances compel allusion to them, they will be minimised as much as possible, and thrust away into obscurity near the poet's corner. This is what happened in regard to a shocking business which occurred recently at Leigh. According to a local paper, a horse attached to a cart took fright, goodness knows what at (no one ever does know exactly what frightens a horse), and bowled over a milk float. The horse attached to the float dashed off in turn, and finally caused a third horse to bolt, and the main street of the town accordingly witnessed the interesting phenomenon of no less than three of these trusty quadrupeds all running away at the same time, and creating general havoc together.

THE above information of course was stuffed away, near the quiet corner we refer to, in a local paper, and no notice has been taken of it in the general Press. In the case of Lord Rosebery's accident, of course, some publicity had to be given to it. It is an almost worse, though less absurd, case than the other, for Lord Rosebery is a distinguished and experienced whip. He has driven all his life, and yet he cannot avoid with certainty a dangerous accident when attempting to control these unreliable animals. Everyone will be delighted to hear that Lord Rosebery escaped practically uninjured, a piece of good fortune which is scarcely short of miraculous. Lord Rosebery was driving a two-horse phaeton on his Dalmeny estate on Saturday afternoon, and in turning a corner too sharply, no doubt owing to spasmodic action on the part of the horses, both Lord Rosebery and the page-boy who was with him were pitched out. The horses, of course, then bolted with the over-turned phaeton and ultimately (which "gives furiously to think," as the French say) Lord Rosebery was taken home without trouble or accident in his motor car, which was dispatched to the scene of the accident.

THE 1906 WINTON CARS.

(Continued from page 1498.)

Fig. 6.—The 25-h.p. Winton Car. View of the Chassis from above showing the long central radius and Torque-rod which lies parallel to the Propeller-shaft.

The Frame and Transmission.

PRESSED steel side-members—stayed together with channel cross members—form the main frame, which is supported by semi-elliptic springs, of a peculiar pattern, both in front and at the rear. Each spring is so constructed that it virtually forms two springs of different stiffnesses, and these are mounted in such a way that the upper part comes into play only when the shock or load is more than usually severe. This comparative independence of the upper spring is obtained by making it with long curled ends, and securing it in place by shackles hung at such an angle that the initial upward movement of the axle merely rocks these shackles, and does not

appreciably deflect the spring itself. Owing to the fact, too, that these springs are, in effect, considerably longer than the main springs, due to their curled ends, they are able to act gently and do not therefore cause any very sudden increase in the stiffness of the suspension as a whole—such as might result from the employment of entirely independent buffers. In spite of the fact that the rear springs lie outside, the main frame is, nevertheless, raised well above the ground, for both in front, and behind, the dumb irons are curved very much downwards. At the rear, these dumb irons are especially noticeable, for they form quite a feature of the frame. Between them pass two stay rods which stiffen the

Fig. 8.—The 25-h.p. Winton Car. View showing the ball-and-socket Thrust Block, Q¹, for the combined Radius-rod and Torque-rod, Q. The Thrust Block is, it will be noticed, set in line with the universal joint of the propeller-shaft, and is stayed to the side of the frame by the Rod, Q².

Fig. 9.—The 25-h.p. Winton Car. View of the back axle, showing the Stay-rod, R, the Brake-rod, S¹, and the combined Radius- and Torque-rod, Q. The upper half of the central portion of the axle casing is easily removable for access to the differential, which may be removed bodily after withdrawing the halves of the live-axle.

Fig. 7.—The 25-h.p. Winton Car.—View showing the suspension of the frame at the rear, and also the method of carrying the wheels on the projecting ends of the axle-casing. On the right the wheel is shown in place with the live-axle removed. Below is one half of the live-axle itself, complete with the jaw coupling, by which it drives the wheel, and just above this is the dust cap which screws on to the hub. Timken roller-bearings are used in the hubs, and these being conical also act as thrust collars.

frame in that region, and at the same time one of them serves as a support to the cylindrical petrol tank. It is interesting to note, too, in connection with the construction of the frame, that the side-members are perfectly straight, and not bent towards one another near the dash as is now the case on most cars. At the same time, however, a very free steering lock is available, for the frame is not of any very great width.

It is not often that any firm makes any self-evident radical departure in the materials used in the construction of the most important parts of their chassis, so the new front axle, made of manganese bronze, which the Winton Company have introduced on their latest model,

could hardly have failed to attract the interest of every visitor who saw this unique departure at the Olympia Exhibition. It has not been adopted, however, with any idea of revolutionising the axle trade, but merely as the outcome of the Winton Company's deep-rooted policy of making everything they possibly can in their own factory. Experiment has shown them that they can cast an axle in manganese bronze which they consider satisfactory, and this, therefore, they prefer to do, rather than build one up, or rely on solid forgings obtained elsewhere. The axle is cast with socket ends which carry the steering-heads on ball-thrust-bearings. A screw-and-nut device is employed for the steering-gear itself, and the road-wheels are mounted on Timken conical roller-bearings.

Similar bearings are used in the hubs of the rear wheels, which run on extensions of the axle-casing in order to relieve the live-axle itself of everything but the torsional driving strain. In order to render the differential accessible, the axle-casing is made in four parts, the two central portions being connected with a horizontal joint so that the top part may be removed for inspection without disturbing anything else. Beneath the axle-casing is an adjustable stay-rod, R (shown displaced in Fig. 11 for convenience), which relieves the sagging strain on the bolts used to fasten the parts of the casing together. Timken bearings support the differential shell, and also take the side-thrust, but a long plain bearing and a fibre thrust-collar are employed behind the driving bevel-pinion on the end of the propeller-shaft. No side radius-rods are used to tie the axle to the frame, but there is, instead, one central rod, Q, which is arranged alongside the propeller-shaft, and terminates at its upper end in a ball-and-socket thrust-block attached to one of the transverse-members of the frame. This thrust-block and the universal-joint at the top end of the propeller-shaft are in line with one another, and thus allow the axle to rise and fall without telescoping the propeller-shaft into its joints. As a matter of fact, however, ample provision for longitudinal motion is made in the universal-joints employed on the chassis.

(To be continued.)

AT OLYMPIA.—The 18-h.p. Gladiator Chassis.—Plan showing the 1906 Model, in which a "Mercedes" Gear, Pressed Steel Frame, and Honeycomb Radiator are important new features. In general design the chassis is similar to that of last year, and a description of the leading characteristics of this chassis together with other matter relating to the new Gladiator models, appeared in our issue of November 18th.

THE "S 41" TYPE PETROL OMNIBUS.

AMONG the motor 'buses supplied by the Motor Car Emporium, that known as the "S 41" type is principally notable for the manner in which the engine may be used, when required, as a brake. In a petrol engine, which is not specially fitted up for the purpose, no really effective braking effect is obtainable, because the retarding effect of

—is given in Fig. 4. The frame is of channel steel, and is carried by semi-elliptic springs, both in front and behind. Those at the rear lie outside, and both ends are carried in guide brackets, which are riveted to the frame. The back axle is tied to the frame by adjustable radius-rods, and the rear wheels, which are mounted on ball

Fig. 1.—Side view of the "S 41" type chassis for a double-decked 'bus.

compression is neutralised by the driving effect of the subsequent expansion, and the net result is little more than that due to friction alone. If, however, the exhaust-valve cam-shaft can be set, so that the compressed air in the cylinder is released into the exhaust-pipe as soon as the piston reaches its "dead-centre," then no power is returned to the engine on the downward stroke of the piston, and the net braking effect is that due to compression, as well as that due to friction. The engines on the "S 41" type 'buses have been fitted up in this manner, and the driver is thus enabled to control the speed of the vehicle almost entirely by means of the small hand-lever which works over a quadrant above the steering-wheel.

In general design the chassis of these 'buses follow ordinary construction. They are of the chain-driven type, are fitted with a gear-box of the Mercedes pattern, which gives four forward speeds and a reverse, and have a 4-cylinder engine capable of developing about 32-h.p. A view, showing the chassis from the side, is given in Fig. 1, and views of the engine from either side are reproduced in Figs. 2 and 3, while a larger view of the throttle-levers on the carburettor — which form an important part of the "air-brake" mechanism

bearings, are shod with Sirdar twin tyres. A peculiar feature of the large chain-wheels is that every alternate tooth is cut away, the idea being that it is useless to have a greater number of teeth in operation at a time on the chain-wheels than on the sprockets. The chains are composed of an odd number of links in order to neutralise the uneven wear which might otherwise take place on them from this arrangement. The engine is connected to the gear-box, in which ball bearings are employed, through an ordinary cone-clutch and a long propeller-shaft, which has a flexible coupling at the rear end. A band-brake, operated by foot, is fitted to the differential countershaft, and internal expanding brakes, operated by hand, are fitted to the hubs of the rear wheels.

Both engine and transmission-mechanism are well protected by a metal apron, which extends as far back as the gear-box, and there is a substantial bent rail, which projects in front of the frame to act as a kind of buffer.

The 4-cylinder engine has its cylinders cast in pairs, and its crank-chamber in one piece—with flanged ends.

Ball bearings are used on the crank-shaft, as also throughout the transmission. The inspection plugs over the inlet-valves are fitted with ignition-plugs, which are provided

Fig. 2.—View of the 32-h.p. engine from the inlet-valve side, showing the positions of the carburettor, A, the magneto, F, and the circulating pump, E.

Fig. 3.—View of the 32-h.p. engine from the exhaust-valve side, showing the positions of the air-chamber, E¹, on the water pipe, the automatic-valve, K, for the pressure feed, and the filler cap, H, on the lubricating oil tank.

in duplicate, one set being permanently connected to the high-tension magneto, F, while the other set is used in conjunction with the accumulators and induction-coil. The gear-wheels, driving the cam-shafts, are enclosed, and are situated in front of the engine. The radiator has a similar appearance to those of the honeycomb type, but it is not constructed of tubes. Thin corrugated strips of brass are used instead, and these are soldered together, in pairs, to form flat tubes. The tubes, thus formed, are assembled so that the cooling water can flow downwards through them and the air can pass freely between them. Behind the radiator is a belt-driven fan, and mounted on the fan spindle is the circulating-pump, E. The bracket carrying the fan spindle is mounted on springs, so that any stretching of the belt is automatically taken up. The circulating-pump delivers the cooling water to the centre of a branched pipe which feeds both water jackets, and, just above the junction between these pipes, there is a small air-chamber, E¹, for the purpose of steadying the pointer of the manometer, on the dash.

The petrol is carried in a tank at the back of the frame, and the lubricating oil, in a tank which lies under the bonnet, but which can be filled from the outside by removing the screw cap, H (Fig. 3). Pressure is maintained in both tanks by the exhaust gases from the engine, and the automatic-valve, K, controls the pressure to both tanks. The petrol passes through the ordinary type of float-feed chamber, A, on its way to the jet in the mixing-chamber, A¹, and the supply of mixture to the induction-pipe, A², is regulated by the throttle-valve, A³. The throttle-valve, A³, is under the driver's control, by means of the hand-lever above the steering-wheel. This hand-lever is connected to the vertical rod, B, which it moves up and down.

The rod, B, acts upon the throttle-valve, A³, through the bell-crank-lever-arms, B¹ and B². Simultaneously with the closing of the throttle, a lever, C—which is connected with the lever, B¹—operates a rod, C¹, which alters the lift of the inlet-valves by sliding tapered cams on the cam-shaft. The lever, B¹, it will be noticed, is so connected with the rod, B, that it may be moved downwards independently. This freedom is necessary because the engine is fitted with a governor, which acts on the throttle through the rod, C¹, and the lever arm, C. The governor is, however, only capable of *closing* the throttle, and a spring, B³, is, therefore, fitted in order to open it again, when the governor has ceased to act on it.

If the hand-lever above the steering-wheel be moved still further round the quadrant, after the throttle is closed, it causes an arm, B⁴, mounted on the end of the rod, B, to come into contact with the spindle, A⁴, which it then pushes

Fig. 4.—View showing some of the mechanism used in connection with the "air-brake" on the 32-h.p. engine of the "S 41" type chassis. The positions of the throttle-valve, A³; the petrol cut-off valve, A¹; and the rod, C¹, operating the variable lift of the inlet-valves, are prominent in this photograph.

down, and so closes the petrol jet. At the same time the throttle-valve, which continues to be carried downwards by the rod, B, uncovers the throttle-valve ports again, and pure air can then be drawn into the cylinder during the suction-stroke. A still further movement of the hand-lever brings into operation a rod, D, which rocks over the exhaust-valve cam-shaft, so that the exhaust-valves open at the end of the compression-stroke. In this position, the engine acts as a brake, for air is drawn into the cylinders during the suction-stroke, then compressed, and finally released just as the piston reaches the "dead-centre" at the end of the compression-

stroke. As the exhaust-valve remains open during the subsequent downward stroke, the piston, therefore, draws in air, which is compressed during the return-stroke, and released by the opening of the inlet-valves. Every upward stroke of the piston is, therefore, a compression-stroke, and the exhaust-valves and inlet-valves act, in turn, as relief-valves to the compressed charge.

The "air-brake" is, of course, only useful as a means of control so long as the 'bus can be kept in motion, because it is the momentum of the vehicle which restarts the engine when the "mixture" is once more admitted to the cylinders. If the clutch were disengaged with the "air-brake" on, then the engine would stop, and if the vehicle were at the same time brought to rest, then the

engine would have to be re-started by hand, because the absence of "mixture" in the cylinders, would prevent their being restarted on the switch.

Table of Reference Letters for the Motor Car Emporium 'Bus.

THE THORNYCROFT INDUSTRIAL VEHICLES—SOME NEW MODELS.

Two entirely new designs have recently been introduced by Messrs. J. I. Thornycroft and Co., both of which were exhibited at the Olympia Exhibition. The smaller chassis has a 20-h.p. engine, and is intended for vans or luries carrying loads of about a ton, while the other has a 24-h.p. engine, and is built specially for double-deck omnibuses. Totally different as they are from one another, they are both extremely interesting examples of up-to-date design, while many of the radically novel departures from previous practice have a special significance since they are obviously the result of the prolonged experience of this well-known firm with industrial vehicles of all kinds. It is the transmission and suspension systems that chiefly attract attention.

The one-ton chassis has a stationary axle, but the central portion passes across from side to side on a much lower level than usual, while above it, and fixed to it at each end, is a completely enclosed differential countershaft. The countershaft is sufficiently above the centre of the road-wheels to permit the spur-pinions at each end to lie inside the internally-toothed gear-rings which are fixed to the hubs, and the wheels are driven by this gear mechanism. In the same way that the live-axle on an ordinary touring car is driven by a propeller-shaft, so is the countershaft connected up to the gear-box on this vehicle, and it has its bevel-gearing enclosed in a neat central case.

Most careful consideration has evidently been given to the question of radius-rods and torque-rods for taking the driving strains and the twisting strains in a satisfactory manner without interfering with the suspension. From the stationary axle, one long armoured-wood bar passes up centrally to the gear-box, and, encircling the tubes that contain the differential countershaft, there are two radius-rods which are anchored at their forward ends to the frame.

No "spring-drive" is fitted, the chassis differing in this respect from all previous Thornycroft models, but

doubtless this particular transmission system with its tie-rods is relied upon to provide its own shock-absorbing parts.

Side chains are employed on the new 'bus chassis for driving the road-wheels on the stationary rear-axle, and, in the main, the design is similar to that of most chain-driven cars. The differential countershaft, however, is completely enclosed, and its tubular casing is mounted freely in plain sockets at each end. Between the countershaft—i.e. the bevel-driven differential-gear—and the change-speed-gear is a flexibly-jointed longitudinal shaft, and between the external casing and the frame of the chassis is a torque-rod; the torque-rod alone anchors this casing, and takes all twisting strains imposed upon it by the reaction of the "drive." In turn, the back-axle is itself tied to the chassis proper by a pair of radius-rods that encircle it at their rear-ends, and encircle the countershaft casing at their other ends.

Between the axle and the frame, is an inverted transverse spring, the ends of which carry the rear ends of the semi-elliptic side-springs. In the way of brakes, one pair act direct upon the sprocket-wheels at the ends of the differential countershaft, another pair—of the expanding type—are fitted to the hubs of the road-wheels.

These two new models do not replace the single-chain chassis made by the firm, but only constitute additional types; they are only provided with three forward "speeds," as against four in the earlier vehicle.

A 5-ton petrol chassis is, we learn, also being built, in which the power is transmitted to the live-axle in much the same way that it always has been on the Thornycroft steam luries. In this form of transmission, a pair of double helical gear-wheels serve for the final drive to the differential, the pinion being connected with the frame-carried portion of the mechanism by a universally-jointed transverse-shaft.

THE Scottish Automobile Club has been timing various electric trams in Scotland, the measurements being made by Mr. D. Eason Hamilton, and checked by the official timekeeper, Mr. A. G. Rennie. The results show that the maximum speeds vary from 17.33 miles per hour between Hamilton and Larkhall, to as much as 21.4 miles per hour in Glasgow.

ONE more automobile publication has been added to the list of those appearing on the other side of the Channel. The first number of *L'Automotion*—an illustrated review of automobilism—appeared on the 1st of the month. In a prefatory notice the new journal declares that absolute truth and sincerity will be its guiding principles.

AT OLYMPIA.—View of one of the new Minerva Chassis, which are now of the live-axle type. In almost every respect the 1906 models differ from those which have preceded them, their leading characteristics now being a pressed-steel frame, ball bearings in the gear-box, two ignition systems, and thermo-syphon cooling.

AT OLYMPIA.—View of the new Scott-Stirling Omnibus Chassis, which has a 22-h.p. four-cylinder vertical engine placed beneath the driver's feet, and an internal expanding main-clutch. Three forward speeds and a "reverse" are provided by the usual sliding-spur-wheel type of gear-box, and the road-wheels are driven by a live-axle. Owing to the elevated position of the radiator—which does duty for a dash—thermo-syphon cooling is possible, and a circulating pump, therefore, is not fitted.

THE CONSTRUCTION OF MOTOR OMNIBUSES—REQUIREMENTS FOR OBTAINING A CERTIFICATE OF FITNESS.

THE following draft regulations have been issued by the Commissioner of Police of the Metropolis for the guidance of proprietors and owners of public motor omnibuses. Suggestions are asked for by the Commissioner, in the event of any of the clauses being deemed objectionable, and the regulations are, therefore, subject to possible modification. They will not apply to vehicles already actually made, or so far advanced as to be incapable of alteration, all such receiving special consideration in each individual case. We give the proposed regulations in full, so far as they apply to motor omnibuses, but have omitted the conditions from No. 12 to 25, which apply to all Metropolitan stage carriages alike, and which deal with the number of passengers in and out, police number plates, name and address of owners, lighting, advertisements, ventilation, seating arrangements, steps, &c.

Carriages must be submitted to the Metropolitan Police for inspection in a thoroughly good condition, and no carriage will be certified fit for public use unless it is newly painted and varnished. The following conditions must also be strictly complied with :—

1. Stage carriages propelled by mechanical means, and subject to the Light Locomotives Act (59 and 60 Vict., cap 36) and Motor Car Act (3 Edward VII., cap. 36), must comply with the requirements of those Acts, and of the orders of the Local Government Board made in pursuance thereof.

2. Each new type of motor car intended for licensing must be presented at New Scotland Yard for inspection. The proprietor must at the same time produce the certificate of registration, and also one from the maker stating the machinery to be safe and in every way fit for use in a public carriage.

If, on inspection, the car is approved, such approval may extend to all cars of that description, and cars of that type need not be again presented at New Scotland Yard, but may be taken to the usual passing station, provided a certificate from the maker is submitted with each car for licensing, stating that it is in every respect similar to the type already approved.

Should an alteration be made, the same course may be required as for a first inspection.

Should it be deemed necessary, an expert will be employed to advise on the subject. The fee for the expert examination to be deposited by the proprietor with the Commissioner, which fee will be returned if the car is passed without alteration being required.

3. The following measurements for an omnibus with top-deck seats must be adhered to, and the number of passengers to be provided for on such vehicles must in no case exceed 16 inside and 18 outside :—

Chassis.—Height from ground after the body is affixed, minimum 28 ins., maximum 32 in.

Chassis.—Length, maximum 19 ft.

„ Breadth, inside measurement, minimum 38 ins., maximum 48 ins.

„ Clearance of the under parts, including axle as far back as the differential-gear box (where fitted), must be at least 10 ins. when the 'bus is fully loaded.

„ Wheel-base (centre), minimum 12 ft., maximum 13 ft. 6 ins.

„ Wheel track (centre), minimum 5 ft. 6 ins.

Body.—Height inside, minimum 5 ft. 10 ins., maximum 6 ft.

„ from ground to spring of roof, maximum 8 ft. 10 ins.

„ from ground to centre of roof, not to exceed 3 ins. camber.

„ of side guard rails 3 ft., and 18 ins. above the seats.

„ of front and back guard rails 3 ft. 3 ins.

„ Width of body inside between seat backs, minimum 56 ins.

„ from off hind roof seat to back rail, minimum 26 in.

„ Length of platform 36 ins.

„ Steps: one only to be used, which should be about 15 ins. from the ground.

Total length over all not to exceed 22 ft.

NOTE.—Smaller omnibuses to be in proportion to the foregoing measurements.

4. Each carriage must be fitted with at least two independent brakes of sufficient strength that either of them is capable of stopping and holding the carriage under all conditions.

NOTE.—The maintenance of the brakes in perfect order is of the utmost importance, and this will at all times be insisted upon.

5. Each car must be capable of being readily steered, and able to turn a corner without unduly interfering with other traffic.

6. The steering arms, &c., to be of sufficient strength, and as far as possible protected from damage by collision. Where possible they should be in duplicate, to allow of the car being controlled should one part become defective.

7. All wires carrying electric current to be sufficiently insulated and placed so as to be free from danger.

8. Petrol tanks should, if possible, be cylindrical and not rectangular, strong enough to resist pressure, and should, as far as possible, be fixed so that any overflow of petrol does not fall upon woodwork.

9. Driving chains and sprockets to be protected by a suitable guard.

10. Head lights of great brilliancy (such as powerful acetylene lamps) will not be permitted.

11. That at least 16 inches, measuring in a straight line, are allowed for each passenger on every seat, which must be fit and proper and convenient for sitting on.

NOTE.—Though the above conditions may have been complied with, yet, if there be anything in the construction, form, or general appearance which in the opinion of the Commissioner renders the carriage unfit for public use, it will not be licensed.

A Weekly Trap List.—The Automobile Association, which has done so much to relieve the labours of the police on the main roads out of London, particularly the highways to Brighton and Portsmouth, is arranging to publish a weekly trap list on the analogy of similar publications provided for the enlightenment of stockbrokers and other “operators.” Members of the Association by an additional subscription of 10s. per annum will regularly receive this useful little compilation which will give “quotations” of all the places near which it is specially desirable not to approach the legal limit of speed. This will, no doubt, further contribute to taking a load off the minds of the police. Those of them engaged in manning any particular trap will only have to obtain a copy of the “weekly trap list,” and on recognising that their particular organisation figures therein, will be able to continue in their umbrageous

thickets, and beneath the “widespreading beeches” on the Ripley Road, that study of the classics which we last week suggested as suitable to the occasion. Possibly, even during the winter when the umbrageous thickets are less agreeable places for reclining under, they may, convinced of the superfluity of their proceedings, return to their ordinary duties, or—as their long continued neglect of these for higher game seems only exceptionally to have been productive of serious consequences—to the enjoyment of domesticity by their own firesides. Even in Great Britain ridicule ultimately kills (though not so quickly as in France), and the amount of ridicule which the arrangements of the Automobile Association are concentrating on the “motor car trap,” is having a decidedly deadly effect. May it soon descend into the grave of former and forgotten methods of exasperating respectable citizens “unknelled, unconfined, and unsung.”

RACES, RECORDS, AND TRIALS.

European Circuit, 1906.—We have in previous issues of the Journal given the bases upon which the A.C. de France Sporting Commission had determined to make the classification in this very important touring event next year, together with other items which were to govern this trial. The full rules are now to hand, and we summarise them below.

The distance is to be 5,000 kilometres, and the trial is to be one of endurance and regularity of running. The organisation is to be primarily under the control of the A.C. de France, in collaboration with the recognised foreign clubs and the leading French clubs. The 5,000 kilometres will be covered in about fourteen stages, varying from 300 to 400 kilometres. In addition, six exhibitions of one day each will be organised at various important cities in France and other European countries through which the competitors will pass. Competing vehicles will be exhibited in these in a special section without charge.

There will be four categories, each determined by the average speed of which the cars are capable, entries in

start, the driver and mechanic of such car will be permitted to enter the garage, the car as from that moment being timed as starting. The car must then be started, and at once driven out of the garage without any replenishments of oil, petrol, or anything else whatsoever, these having to be dealt with outside in the running time of the competitor.

Entries will be received at ordinary fees up to April 15th next. After that date and up to June 1st fees will be doubled. Vehicles driven by any form of mechanical motor are eligible to compete.

The jury will be an international one, and will be composed of representatives of each country in proportion to the number of vehicles engaged. This jury will deal with the particulars supplied by the competitors, will decide the official classing, and will deal with all disqualifications, &c.

The weighing, marking of parts, &c., will take place eight days before the day to start. The chassis will be weighed firstly by itself, including the fuel and oil tanks, and subsequently with the carriage body complete.

	Entrance Fee.	Average Speed per hour.	Maximum Total Piston Area.	Seats.	Style.	Carriage, Body, and Fittings. Min. Weight.	Weight to be Carried.
	francs	kil.	mm ³			kilogs.	kilogs.
Cat. I.	1000	30	86590 = 1 cyl. of 105 mm. bore	2	Petit Duc* ...	75	3'3 per cm ² of piston area
" II.	1500	35	226190 = 2 cyls. of 120 mm. bore	4	Double phaeton† ...	200	2'95 " " "
" III.	2000	40	346360 = 4 cyls. of 105 mm. bore	4	Closed double phaeton	375	2'35 " " "
" IV.	2500	43	530920 = 4 cyls. of 130 mm. bore	4	Limousine ...	450	2'15 " " "

* With hood.

† Without hood.

each category being limited by the surface of the piston or pistons. In each category, in addition to the power of the motors, special regulations will govern the weight of the carriage body and accessories, passengers, the luggage, tools, renewals, &c., in proportion to the power of the engines. The dimensions for each type of carriage body are specified for each class. The classes are given in our table above.

Steam cars will have a special category to themselves. The results will be arrived at according to the regularity of running between the numerous controls.

Cars arriving at the end of a control at an earlier hour than allowed under their average declared speed will be stopped, and they will be re-started at the hour at which, according to their average declared speed, they should have arrived. Cars taking a longer time than that allowed for by their average declared speed will be penalised by one point per minute in excess of such maximum time. A forty-five minutes' wait for *déjeuner* will be enforced, and any car not stopping the full forty-five minutes will be penalised by one point per minute for such time as the car is not stopped.

The cars will be started each day in the reverse order to that in which they arrived the previous day.

Closed "parks" will be strictly enforced throughout. Cars, on their arrival in the official garage, must only have their motors stopped immediately the car is in place. Each morning at the moment when each car is timed to

Change of pneumatic tyres will be permitted, but the number of spares to be carried by the competitor must be declared beforehand, together with the name of the maker, and except the tyres so authorised, no others will be permitted to be used. When any tyre is replaced the old one must be given up to the authorities at the next

AT OLYMPIA.—The 1906 two-seated De Dion Car fitted with 8-h.p. single-cylinder engine, tubular frame, individual clutch gear and stationary rear axle with the wheels driven direct by cardan shafts.

The regulations are to be translated into the language of the several countries through which the route will pass.

Voiturette Competition.—The judges have given their decision in this Paris trial, of which we gave particulars in our last issue. It will be remembered that, during the first stage of the last day's reliability run, an enormous number of nails had been maliciously scattered on the route over which the competing cars passed, with the result that they one and all were seriously handicapped and penalised by breakdowns through punctures. Having fully considered the question of annulling this stage under the circumstances, the jury have decided not to annul this section, and under these conditions the official results have been decided as follows, the first place going to the Vulpes car, whilst the De Dion Bouton firm obtained the two next places, as well as the prize for regularity, as announced by us last week :—

	Penalisation Points.
1 Vulpes (Barriaux)	241
2 De Dion Bouton (Lionel De Dion)	327
3 De Dion Bouton (Cormier)	439
4 Lacoste et Battmann (Gachet)	502
5 De Dion Bouton (Bardin)	561
6 Gregoire (Tavenaux)	1,334
7 Lacoste et Battmann (Rochay)	1,726
8 Gregoire (Renoncé)	3,437

AT OLYMPIA.—The 1906 Daimler Car.—Front view showing the neat finned tube radiator, with its aluminium casing, which forms such a distinctive feature of these well-known cars. The straight front-axle is another unusual characteristic.

control, so that the old tyres and tubes may be sent to the Commission at Paris to be identified and checked with the original number of renewals granted. The number of tyres used will be taken into consideration in classing.

Honorary diplomas will be awarded for the endurance tests in each category, in the proportion of one to each five competitors, such awards being given to those five having the least penalisation points. All competitors who arrive within the maximum specified time will receive a diploma. The start will be from the A.C. de

France to hold a Big Race next Year.—Following a resolution of the Chambre Syndicale de l'Automobile that it is desirable that a long speed race should take place in 1906 in France, there is every probability that the A.C. de France will consent to organise such an event during the coming year.

The German Automobile Club have decided, on the other hand, after full consideration that they will not

organise a speed contest on the road for 1906, owing to the fact that the manufacturers are too busy to give the attention to building racing cars.

THE regular Aix-les-Bains long-distance tourist car competition is to be abandoned for 1906.

24-Hour World's Record.—A new record is reported from America as having been made at the Indianapolis mile track, for 1,000 miles and for the 24 hours. The cars timed were two 40-h.p. National 1906 touring cars, stripped. Under the auspices of the Indianapolis Automobile Racing Association, and with the sanction of the American Automobile Association, a start was made at 2.45 p.m. on November 16th, the cars being driven by J. Clemens and C. Merz. Clemens' car, in the 151st mile, came to grief through defective steering apparatus, but although the car was damaged, no other injury occurred. The two drivers from that time took turn and turn about in driving. The first new record time was at the 650th mile, which was timed for 14h. 8m. 51 $\frac{3}{4}$ s. The 1,000 miles were run in 21h. 58m. 0 $\frac{1}{2}$ s., beating Vaughan's previous record for the distance by 1h. 35m. 19 $\frac{1}{2}$ s. The distance covered in 24 hours was 1,094 $\frac{3}{8}$ miles, this exceeding Vaughan's distance by 78 $\frac{3}{8}$ miles. The finish was at 2.45 p.m. on November 17th. The chief intermediate new record times were:—

Miles.	h.	m.	s.	Miles.	h.	m.	s.
650 ...	14	8	51 $\frac{3}{4}$	850 ...	18	23	44 $\frac{3}{4}$
700 ...	15	10	29 $\frac{3}{4}$	900 ...	19	44	48 $\frac{1}{2}$
750 ...	16	20	25 $\frac{1}{2}$	950 ...	20	54	50 $\frac{3}{4}$
800 ...	17	17	26 $\frac{1}{2}$	1,000 ...	21	58	0 $\frac{1}{2}$

The average speed was about 45 $\frac{1}{2}$ miles an hour, and the best mile was timed for 1 min. 2 $\frac{3}{4}$ secs.

MONT VENTOUX Hill Climb is announced to be held on September 15th and 16th of next year.

THE Milan A.C. announce an important tourist car competition for next year, with a grand prize to be termed the Gold Cup. The distance for the trial, to be run in the spring of 1906, will be 4,000 kiloms. Valuable money prizes will be given in addition to Cups.

ACCORDING to the *Blackpool Herald*, the prospect of further racing on Blackpool Promenade is extremely poor. Our contemporary states that it may be safely concluded that Blackpool has seen the last of its motor speed trials, and that "in the future the nurturing of the motor interests in Blackpool is to be left to the motorists themselves, whose friendly trips into the country cannot possibly aggravate or inconvenience any section of the Blackpool public."

Goggle Competition.—The judges announce their decision in respect to the goggles sent in for competition to the A.C. de France. M. Georges Huillier secures the Duc de Valencay's prize, and Mr. G. Cormier's prize is divided between M. Feriol and M. Lataste.

Théry Retires.—"I am resting on my laurels," said the elderly gentleman, when he clapped on the brakes too suddenly just as he arrived at his front door, and was accordingly precipitated from his automobile into the middle of his laurel bush, and the celebrated Théry has made use of the same expression, though he has never had a serious accident. He has now finally decided he will take part in no more automobile races.

AT OLYMPIA.—Views of the 9-h.p. and 12-h.p. Globe Cars, the special features on which are the Hitchon Gear, the worm-driven Back-axle, and the inverted elliptic transverse Spring which forms the only suspension for the frame at the rear. The smaller model has a single-cylinder Engine, but there are four cylinders on the engine of the larger car. The Gear-box is of the sliding spur-wheel type, but a system of free-wheel clutches is introduced in order to make changing speed easier. A description of this gear appeared in our issue of February 27th, 1904.

He has steered the cars of his firm to victory, and came in a good first in the four greatest automobile races the world has seen, he has not recently been beaten, and now he is determined that he will remain unconquered. Cincinnatus went back to his plough after he had saved Rome, so Théry is going back to his bench in the workshop from which he emerged to world-wide celebrity. This is a wise decision, and has something fine about it, too. One of the charms of Théry's character has always been that all his successes have never made him adopt

the slightest difference in his attitude to his fellow-workmen with whom, once upon a time, he used to work at the bench. He has netted nearly £10,000 by his great victories, and as he is very frugal and still resides in the same rooms he occupied before he achieved universal fame, and, as he is a highly-skilled workman, he has not much fear for the future. The great thing to know is when to leave off, and few people learn the lesson. We wonder if Théry will be wise enough to keep to his sensible resolution

MOTOR BOATING.

THE competition for the "Coupe du Salon" for motor boats had, at the last minute, to be postponed from December 3rd until December 31st, owing to the dangerous state of the stream in the Seine above Paris. The necessary sanction of the river authorities has been given for the races to take place.

THE Marquis de Dion is having what he terms a "floating villa" built to order. It appears to all intents and purposes to be a large motor-driven house-boat; in fact, the only difference would seem to be that the Marquis de Dion refuses to call it by that name. It is 100 ft. long, very broad, and of shallow draft, and it can be driven by its motors about six miles an hour. The Marquis de Dion intends to drive his "motor-villa-boat" or "villa-motor-boat" up the Seine when he has business for any length of time in Paris, and live on the Seine near the capital, and when he wants to go anywhere else, for example to Monte Carlo, he will have the motor-boat-villa forwarded by water; in this way the Marquis will always be able to be, as an advertisement says, "At home, from home," and as he is taking a couple of motor cars on board, he will be able to explore the neighbourhood of any spot he stops at.

MESSRS. GAUTHIER AND Co. have good reason to lament the bad luck which has too often attended motor racing boats, for a specially unfortunate slice of it has been portioned out to the 50-h.p. Rochet-Schneider, 30-feet cruiser, which was to have been exhibited by them at the Olympia Show, subsequently going on to the Paris Exhibition. She has had her first and last experience of the water. Her builders, Messrs. Gallinari and Co., of Leghorn, shipped her for London, for the sake of safety, on board a small steamer. Bad weather was encountered in "the Bay," and the captain of the steamboat believing or stating his vessel to be in danger, promptly jettisoned his motor-driven rival, which dived head first into the stormy water, and promptly disappeared from view, making a journey to the bottom in no doubt record time.

MESSRS. S. F. EDGE, LIMITED, have sent us a most attractive booklet describing the various trips and exploits of Napier Major. The letterpress of the publication consists of a brightly written account of the various journeys which Napier Major has undertaken, and to which copious reference has been made in our columns. The numerous incidents on various tours are illustrated by photographic reproductions of the places and people visited.

The 16-20-h.p. Humber Car.—View (on the left) showing the lower half of the Gear-box, with the gears and operating-rods in place. Four forward speeds, with a direct top gear, are provided by means of two sliding members which are operated on the Mercedes principle. The "reverse" is also independently operated by a separate sliding gear-wheel below the lay-shaft. Plain bearings which are ring-lubricated are fitted to all shafts, but an important feature in the construction is the provision of an additional ball-bearing, B, to maintain true alignment at all times between the driven and driving shafts. On the right is a view of the Engine of the 16-20-h.p. Humber Car from the exhaust-valve side, showing the position of the Eisemann High-tension Magneto. The Commutator, A, which is mounted on an inclined Spindle, is partly visible.

AERONAUTICS.

Brothers Wright Rumours.—A sensational statement appears in the columns of our French contemporary, *L'Auto*, for the 1st inst. The French paper declares that during the course of last autumn the Brothers Wright, with whose names, as the most intrepid and advanced experimenters in aerial free flight, all our readers have long been familiar, have executed flights, varying in length from just under 18 kiloms. up to 39 kiloms., with a motor-driven aeroplane, returning to the point of departure, and averaging a speed of 1 kilom. per minute. This simply means in plain English (and it can mean nothing else, if true) that the Brothers Wright have definitely solved the problem of aerial navigation on the heavier-than-air principle.

The source of the information is said to be a letter written personally by the Brothers Wright to the well-known French aeroplane experimenter, Captain Ferber, with whom they have been in regular correspondence—the letter also stating that they are willing to dispose of their invention to the French Government for “un million.”

It is no wonder that universal excitement in aeronautical circles (and beyond them) reigns, but there is a considerable degree of scepticism regarding the tidings. Much as one hopes that they may be true, or, at any rate, enclose nucleus of solid fact, it is impossible to avoid profound scepticism—scepticism which is expressed very forcibly in a letter by M. Archdeacon, who is himself an experimenter on the same lines, and knows what he is talking about.

Both he and others point out that it is, at any rate, an exceedingly remarkable circumstance that not a word on the subject should, as far as can be ascertained, have appeared in the Transatlantic Press. If such sensational and tremendously important experiments were being conducted in a not very remote part of the States, on a subject in which almost everybody feels the most profound interest, is it possible to believe that the enterprising American reporter, who, it is well known, comes down the chimney when the door is locked in his face—even if he has to scale a fifteen storey sky-scraper to do so—would not have ascertained all about them and published them broadcast long ago? And why should France be the most favoured nation? Why particularly, as is further alleged, should the Wrights desire to sell their invention to the French Government? Surely their own is the first to which they would be likely to apply. But this is not the only feature of the situation which raises suspicion. There is the question, what have the Wrights got to sell? That they could obtain valuable patents for their machine is, unfortunately, very doubtful. It is their skill and their resource, and that alone, which have enabled them hitherto to effect the triumphs which we know them to have accomplished. Their apparatus may present features of novelty, but it is reasonably certain that even their old non-motor-driven apparatus was one which nobody but the Wright Brothers themselves could succeed in using. It was like the bow of Ulysses, which only he could wield. Skill and manual dexterity slowly learned through a hundred failures cannot be sold, and cannot even be communicated. The first reptile which, sometime in the Jurassic or Triassic age, fleeing in front of a hotly-pursuing Plesiosaurus, found that he could toboggan down a plane of air on his membranous fore-legs, and gradually learned how to do it, was probably able to hand on his acquired knowledge to his progeny,

and in some such way, no doubt, the race of Pterodactyls was evolved. Skill of the kind the Wrights appear to have developed can be inherited, but it can scarcely be communicated—far less sold; and they are not the sort of men one associates either with pecuniary graspingness or empty bluff. It seems quite certain, at any rate, from our French contemporary, that Capt. Ferber has received a letter from them declaring that they have been successful, but at present that is about all we really know, and must wait in patience for further disclosures. Doubtless, we shall soon know the real facts of the matter, for the publications in *L'Auto* are exciting such an amount of attention that it will be impossible for the Brothers Wright to permanently maintain their usual Sphinx-like silence.

FROM information conveyed to the Press by Mr. Rawson, who, it will be remembered, was associated with Dr. Barton in the building of the airship which was so long a permanent feature in the grounds of the Alexandra Palace, it appears that a “client of his” has invented a machine of the aeroplane type which will only cost £150 to build, and will have a lifting power of 250 lbs. per horse-power employed in it. It is also said to be thoroughly controllable and manœuvrable, at least this is what is concluded from the behaviour of a model some 4 ft. square. Unfortunately a good deal of allowance has to be made when results obtained with models of this size are applied to machines on a larger scale. Mr. Rawson appears to look upon this new flying machine as having solved the problem of aerial navigation. We hope his view may prove to be correct.

COUNT ZEPPELIN has made a further ascent with his airship on Lake Constance. At the start an accident occurred to the motor, but after that was put right he was able to continue his experiments, executing numerous curves with the navigable balloon. Altogether eleven passengers occupied the car, and Count Zeppelin declares himself thoroughly satisfied with the results.

MOTOR CYCLING.

Auto-Cycle Club Fixtures for 1906.—The provisional list of fixtures for next year has been issued by this club, and includes the following:—

January	...	First Quarterly Trial.
May	...	Open Hill-climb.
“	...	Selection Trials for International Cup.
“	...	International Cup Race.
“	...	Tour to Austria.
“	...	Land's End to John o' Groat's Trial.
July or August...	...	Penalty Run.
August...	...	Annual Six Day's Reliability Trial.
September	...	Consumption Trial.
“	...	Annual Race Meeting.
October	...	Passenger Motor Cycle Trial.

The Land's End to John o' Groat's event, which is open to all types of motor cycles, should be the means of obtaining much interesting data, as the competitions of this club are usually carried out on extremely sound and practical lines. The details of this event have not yet been settled and possibly, therefore, suggestions might be made by those interested, so that the committee of the club may take them fully into consideration when dealing with the regulations governing the trial.

The Tour de France.—The itinerary of this motor cycle event of the Auto Cycle Club of France, to be held from May 13th to 14th next year, is now officially confirmed with the daily routes given by us in our issue of November 18th. The total distance of the tour will be 2,723 kilometres.

CLUBS AND ASSOCIATIONS.

The British Empire Motor Trades Alliance. First Annual Dinner.—On Monday last, the 4th inst., the Alliance held their first annual dinner, at the Holborn Restaurant, with Mr. H. Austin in the Chair. It is likely—and it is surely to be hoped—that this first dinner of a society, founded for the furtherance of the British automobile industry, will, in years to come, be looked upon as an historical event in the annals of automobilism. This is not so much for what the function was, as for what it portended, and for the views expressed by prominent men present about their outlook on the industry. There can have been few of those who attended who had not at some time in their careers handled foreign cars in the English market, and as Mr. S. F. Edge said, when replying to the toast of "The British Industry," it was to their credit to have done so, seeing it was due to their having conducted profitable businesses then that they were now so well able to encourage home productions. There was a time when foreign cars were fashionable merely because they were foreign cars, but this, Mr. Edge said, was more than on the wane, in fact, he felt quite convinced, since the Olympia Show this year, that the time had come when of two equally priced cars, the prospective purchaser gave preference to that of English construction. There are many other signs of the times, too, which have an important bearing on the British industry, and Mr. Edge did not fail to draw attention to the fact, which is occasionally overlooked, that for some time past the British industry has been increasing out of proportion to the importation of foreign cars, and that there is every prospect of finding next year's returns showing an actual superiority in money value. To carry the question even further, there is now a demand for English cars abroad, and although at the present moment the duty in France is not exorbitant, yet it might not be long before English firms would find that the only way they could profitably sell their cars in that country, would be to construct them there—in which case, of course, the French, and not the English, workmen would get the benefit.

There is always a fascination about a clean sweep, and Mr. C. S. Rolls drew attention to the desirability of giving particular encouragement to the manufacture of British accessories by specifying the use of English made lamps horns and other fittings on entirely British cars. In this Mr. Austin concurred, and he further drew attention to the fact that although it might appear to be a small matter, yet as the present importation reached a value of £500,000, it was obviously a section of the industry worth more attention.

Not unnaturally the question of a separate Exhibition for British cars formed a theme in most speeches, but on the whole opinion was in favour of showing English made goods against those which are imported, as is done at the present time. Mr. Austin, especially, was careful to urge the fact that the new institution was in alliance with, not antagonistic to, the Society of Motor Manufacturers and Traders, and Mr. Sidney Straker, president of that society (who replied to the toast of the guests), expressed it as his opinion that the question of a separate show was one which could not help coming to a natural head in due course, and that it would then be more a case of necessity than of desirability. Incidentally, too, Mr. Straker referred to the large amount of British capital invested in the importation of foreign made cars into this country as a matter which should not be overlooked.

Speaking about the practical organisation of the B.F.M.T.A., Mr. Claude Johnson made several important suggestions which showed a laudable anxiety that the institution should be more than merely sentimental. One of these was the establishment of a Paris correspondent, who should keep in touch with French progress, and especially with the questions of entry into French-organised International Trials. In several other points—such as the matter of special awards to British cars in the Tourist Trophy Race—Mr. Johnson pointed out where the theoretical objects of the society might find a practical application. In its outlook on automobilism, Mr. Johnson likened the B.F.M.T.A. to the A.C. de France, which, he said, acted solely for the French industry, and not for automobilism as a whole, as the A.C.G.B.I. is forced to do, on account of its different constitution.

DURING last month several members were elected to life membership of the Motor Union, including the Right Hon. Viscount Newport, of Shifnal, Mr. S. F. H. Endie, of London, and Mr. A. Aston Talbot, of Llyswen, Breconshire. It is surprising that more automobilists do not avail themselves of the privileges which life membership to the Union confers, considering the smallness of the contribution, which is ten guineas.

British Motor Boat Club.—The first Annual Dinner of this enterprising club took place last week at the Hotel Cecil, when the Commodore, Admiral Sir William Kennedy, K.C.B., occupied the Chair. About eighty guests were present, and the function resulted in an extremely pleasant evening for all concerned.

Following the usual loyal toasts, which were enthusiastically received, extra acclamation being accorded to that of Her Majesty the Queen, in consequence of the day chosen being identical with her birthday,

Sir Boverton Redwood proposed the principal toast of the evening, "The British Motor Boat Club." He thought that very few clubs had a better *raison d'être* than this club. In the present early days of motor boating, such a club could confer exceptional advantages upon its members by exercising a guiding hand in developing the sport and pastime by means of racing and competitions, leading thereby to the evolution of the perfect motor cruiser and pleasure boat. The motor boat, he was convinced, had an immense future before it from the utilitarian standpoint.

Admiral Sir William Kennedy, in replying with much enthusiasm, said that he was extremely glad to give the club—which now numbered 140 members—as far as possible a helping hand, and with that object in view he was able to influence the great privilege which was conceded by the Admiralty of members being permitted to fly the blue ensign, putting them for the time being on a level with a man-of-war. He felt sure it was only red-tapeism that had prevented them from being permitted the prefix of "Royal" to their club's title. Possibly when they had done something great to distinguish themselves they might still hope for that honour. It was, he said, a great source of gratification to them all that amongst the guests were Sir Evan McGregor, K.C.B., the Secretary of the Admiralty, and Lady McGregor, who had consented to distribute later the valuable prizes which had been won during the past season. The interest which the Admiralty was taking in the petrol motor boat, he thought, was strongly emphasised by Sir Evan's presence amongst them that evening. He hoped to see in the future large sea-going vessels propelled by the petrol motor.

In proposing "The Prize Donors," Mr. R. Denys Dundas, the hon. treasurer, stated that he believed in a man having a tangible result for his efforts. For this reason, he suggested that the prizes given by the British Motor Boat Club all the year be in kind, and not take the form of cheques or money prizes. His principal reason for this suggestion was that motor boats are not like yachts, which have large crews.

Mr. Sidney Straker, replying, said he was glad the British Motor Boat Club had decided to enrol themselves as a section of the Society of Motor Manufacturers. Such an action would enable a bold and substantial front to be presented to the enemy, which to-day were very considerable. Among them were the Thames Conservancy, which was a thorn in the side of the motor boat. Therefore it was with very great pleasure that he was able to say that the Society had an affiliation arrangement with every body connected with automobilism.

In announcing that Lady McGregor would present the prizes, the Commodore said that Mr. Mawdsley Brooke had wired offering another Cup in place of the Brooke Trophy which had been won.

After the presentation of prizes had been made, Mr. Oswald Colls proposed the toast of "The Ladies and Visitors," coupling with it the name of Miss Annesley Kenealy.

A charming programme of songs and music was provided by the hosts, amongst others who were welcomed with no small appreciation by old friends being Mr. Charles Coborn.

Essex Beaumont Motor Club.—On Thursday, November 30th, at "Castle" Hotel, Woodford, a very interesting paper on the construction of a motor cycle engine was given before a large attendance of members by Mr. A. E. Lowe. Some examples of work made by Messrs. Prestwich and Co. were exhibited, and every part necessary to complete a motor cycle engine was shown, both in the rough casting and the high finished state ready for assembling. Mr. Lowe succeeded in securing the undivided attention of everyone present by explaining the technicalities in such a simple way.

Essex County A.C.—A general meeting of Essex automobilists took place on November 29th, at the Great Eastern Hotel, Bishopsgate Street, when it was formally decided to found an automobile club for the county, to be known as the "Essex County Automobile Club." The following permanent officials were duly elected:—President, the Earl of Warwick; vice-presidents, Col. Lockwood, M.P., and Col. Tufnell, J.P., D.L.; chairman, Mr. Burnett Tabrum, J.P.; auditors, Mr. W. Wynn and Mr. H. E. Halsey; hon. treasurer, Mr. W. Arckwright; hon. secretary, Mr. E. C. Tijou, 26, Great Tower Street, E.C.

Leicestershire A.C.—On Friday last week the third annual dinner of this club took place at the Grand Hotel, Leicester, when Mr. E. G. Mawbey, M.I.C.E., presided, and amongst those present were:—Hon. A. Stanley, M.P., Sir Herbert Marshall, J.P., Mr. W. B. du Pre, Colonel Powell, Captain W. Byron, Dr. Tuckett, Messrs. Moresby White, Claude Johnson, G. Goode, W. Rees Jeffreys, T. W. Lumley, C. Bennion, J.P., Booth Granger, J. McAlpin, Orson Wright, Dr. Pemberton Peake, Dr. McAllister-Hewlings, Councillor W. W. Coltman, Dr. Mitchell, Dr. Edwards, Messrs. M., P. and A. Mawbey, H. H. Wildt, H. Wildt, T. Prentice, G. Thompstone, J. A. Doran, L. Pierpoint, D. McAlpin, A. E. King, W. Harding, J. Bennett, J. Rollston, W. Taylor, J. Harris, A. P. Carryer, R. Sutton Clifford, W. Hodgson, A. H. Faulkner, J. P. Jones, T. C. King, A. McAlpin, hon. sec.

In proposing the toast of the A.C.G.B.I. and Motor Union, Mr. W. B. du Pre said that motoring, which ten years ago started purely and simply as a sport, had now developed into an industry and a commercial undertaking which was likely to change the whole face of social, economic and commercial life. He looked forward to motorists securing the abolition of the speed limit in the open country, combined with enforcements of strict regulations and penalties against dangerous driving in villages and towns, and congested traffic.

The Hon. Arthur Stanley, M.P., the chairman of the A.C.G.B.I. and Motor Union, in replying, said personally he had no fear about legislation, as he believed they had reached the low water mark in the Act now in force.

Mr. W. Rees Jeffreys, the secretary of the Motor Union, in responding on behalf of the Union, expressed his conviction that no legislation would be able to stop the motor car movement, because it had struck its roots too deeply in the country, and meant so much to the people that nothing short of prohibition by Act of Parliament could stop it.

Mr. Claude Johnson had in his hands the toast of the Leicestershire Club and its President, and he availed himself of this occasion to congratulate the club upon the splendid movement it had inaugurated amongst provincial clubs by taking out the crippled children of Leicester into the country in motor cars.

The Chairman of the club, in responding, stated that the membership of the club now was 100. He spoke highly of the manner in which the chief constables of the borough county had carried out their duty towards motorists. They had acted on broad lines and had not instituted any vexatious prosecutions. The motorists who had done wrong had been convicted and he thought it served them right. He advocated abandoning hill-climbing in public thoroughfares, and holding this class of competition on private grounds only. After careful observations he had come to the conclusion that the much-talked-of damage to roads by motor cars was grossly exaggerated. He found that the damage was very slight, especially where the road was made of good binding material.

Sir Herbert Marshall, in submitting the toast of "The Visitors," pointed out the great advantages which motor cars had conferred. The great thing was to educate the public to the fact that motoring was not in the hands of unreasonable men, and that there was a general desire on the part of motorists to minimise any unpleasantness which might arise from the use of motor cars. He hoped the motor car industry would continue to grow, and advocated the abolishment of the speed limit.

Mr. Moresby White responded, and the toast of the secretaries, Mr. A. McAlpin and Mr. Sutton Clifford, submitted from the chair, was received with acclamation.

THE North Yorkshire Automobile Club was formally launched at a meeting of automobilists at York last week.

WE have received an advance copy of *Punch's Almanack* for 1906 which is almost more effective and amusing than *Punch's Almanack* usually is. A special feature this year is a double-page colour plate by Mr. Bernard Partridge in which "Mr. Punch reviews the fashions of his reign," this being the first occasion on which colour process has ever been used in connection with the paper. Naturally enough, automobilism provides some topics for amusement, though considering the numerous ludicrous incidents that have characterised the development of the motor car, and particularly its conflicts with the police, we are rather disappointed that automobilism is not made more prominent use of, the more so as such excellent cartoons on the subject have appeared from time to time in *Punch* during the past year. However, those that do occur are amusing enough. Particularly is this the case with the drawing of a stuffed aunt in a glass case in a museum of 19 inspected by automobilists of that date, who express their astonishment that such an object allowed to run about the streets and get in the way of automobiles.

THE Automobile Association still continues to do useful work on the Brighton Road, near Surbiton, at Hindhead on the Portsmouth Road, and at the well-known stretch in the Andover district between Hurstbourne Priors and Wallop. They have been so successful, in fact, in the latter district, that the police have been content to leave the control of motor traffic entirely in their hands, the result of which, no doubt, will be that automobilists will not in the near future be called upon to "hand over" the usual munificent contributions to the local rates at the Andover Police Court.

WE knew it was sure to come, the admiration for speed is becoming so universal. A motor omnibus has positively been summoned by the London police for *loitering*! The conductor of a Road Car motor omnibus, which travelled between Piccadilly and Putney, was summoned at the South Western Court one day last week for this offence. The conductor said the car had broken down, which necessitated a long wait. The magistrate—Mr. de Grey—asked the prosecuting policeman whether, if a horse fell and a delay was caused, the police would prosecute, a question which was answered in the negative. Ultimately the magistrate let off the conductor on condition of his paying the costs of the summons.

AT OLYMPIA.—The Duke of Westminster's new Mercedes, exhibited by Messrs. Lawton, who built the luxurious body.

CORRESPONDENCE.

* * The name and address of the writer (not necessarily for publication) MUST in all cases accompany letters intended for insertion, or containing queries.

STEAM CARS IN THE TOURIST TROPHY RACE.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—As a member of the Committee of the Automobile Club has seen fit to attribute my recent letter on the above subject to trade jealousy on my part of a certain car which he favours, may I be permitted to explain that for some years now I have been deeply interested in the organisation of a form of racing in which, instead of the fastest car within certain weight limits winning, the fastest car within certain fuel limits should win. The race for the Tourist Trophy was the first race run under the latter limitation.

The Automobile Club recently published their intention of admitting steam cars to the race for the Tourist Trophy under a different fuel limitation to that which is to apply to petrol cars.

Owing to the interest I have taken in this new form of racing, I gave considerable thought to this proposal and ventured to express my humble opinion that a race run under such conditions might be misleading to the public. I believe members of the Committee of the Automobile Club (except one member who good-humouredly takes chaffing exception to all letters to the Press save his own) appreciate honest criticism of the work of the club.

In order to emphasise my argument that the proposal might result in the club unintentionally causing the public to be misled, I stated that steam cars were admittedly inefficient. My ground for making this statement was that in connection with the race, which is a test of efficiency, the club had been urged to give an extra fuel allowance to steam cars, and the club had admitted the necessity of giving to steam cars a considerably larger fuel allowance than that made to petrol cars to perform the same work.

I believe that when tests are made between Plymouth and Gibraltar with a view to ascertaining the fuel-consumption of warships driven by two different power-generating systems, the terms "efficient" and "inefficient" are used.

I was writing purely of fuel consumption, and my remarks had reference to the quantity of fuel consumed and not the money value of fuel consumed, as the former and not the latter is the basis adopted by the club.

I regret if my use of the word "inefficient" may have been misinterpreted to mean that steam cars are undesirable in any way except in the sense and to the extent to which my letter referred.

Mr. Ashton Jonson is wrong in imagining that my letter had anything to do with trade motives, or that it referred particularly to the make of steam car which he uses. Mr. Ashton Jonson will perhaps kindly remember the keen interest I have taken for years in the question of the new form of racing, and also that there are other steam cars besides the particular steam car which he drives.

I still think that the club, in giving cars of a particular class more fuel than that allotted to other cars in a race in which fuel limitation is the foundation, is not taking the best means to educate the public as to the respective capabilities of various makes of cars. Of course, this is only my humble opinion, and I shall gladly bow to a decision arrived at by the collective wisdom of the committee of the club.

Yours faithfully,

CLAUDE JOHNSON.

Dec. 1st.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Referring to the correspondence that has taken place in your paper of late re the fuel for steam cars in the next Tourist Trophy Race. I notice that most of your correspondents state that the fuel allowance ought to be placed on value of fuel and not on the quantity; therefore, the steam car running on paraffin would be allowed more gallons of fuel than a petrol car. If I remember rightly, I believe the regulations for 1906 allow the steam cars a gallon of paraffin for every 16½ miles; if this is so, I should like to know if I entered a paraffin car whether the A.C.G.B.I. would allow me a gallon of paraffin for every 16½ miles, which I should certainly be entitled to if the fuel allowance was based on value.

Yours faithfully,

J. PERCY DEAN.

Salisbury, Dec. 2.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Mr. Ashton Jonson takes exception to the words, "admittedly inefficient," used by Mr. C. Johnson, when referring to steam cars in the Tourist Trophy Race; can he give any reason for the greatly increased fuel allowance which the committee have decided to give steam cars, other than the admitted inefficiency of the latter?

Yours truly,

CHAS. S. ROLLS.

Dec. 4th.

FOUR AND SIX-CYLINDER CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I have read the correspondence with reference to 4 or 6-cylinder engines with great interest, and as I have had considerable experience with both types, I should like to express my views on the subject.

1. Take two engines, one with six cylinders and one with four cylinders giving equal power, you will not find very much difference in the weight, but probably the 6-cylinder will be heavier than the 4-cylinder.

2. Practically no difference in vibration will be found, and the 4-cylinder will run just as slowly as the 6-cylinder with an equal load; therefore, I do not consider it advisable to make 6-cylinder engines for motor cars, owing to the extra complications and expense.

With reference to the run up the "Cat and Fiddle" Hill by a Rolls-Royce car on the top speed: this car is said to be geared to 37 miles an hour when the engine is running at 1,000 revolutions per minute. I should like to know what power this engine gives at 1,000 revolutions per minute?

I may say that I recently drove a 4-cylinder 22-h.p. Crossley car from Openshaw round by Macclesfield, up the "Cat and Fiddle" Hill to Buxton, and back to Openshaw, all on the top speed and with the greatest ease. This car is geared to 33 miles an hour when the engine is running at 1,000 revolutions per minute.

I believe there are many 4-cylinder cars that will do similar journeys on the top speed, providing they are not geared too high; and I also believe the same of 6-cylinder cars. But why two extra cylinders, when 4-cylinders will do the work just as well as 6-cylinders?

Yours truly,

W. WILSON.

Otto Gas Engine Works, Manchester.

Nov. 29th.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I am always willing to stand corrected when I am in the wrong, but Mr. Edge certainly, in endeavouring to make out his case for the 6-cylinder engine, has not only failed to prove me in the wrong, but at the same time has weakened his own position very considerably by his last letter.

To suggest that a 6-cylinder engine is not heavier than a 4 cylinder engine of the same horse power is, on the face of it, absurd.

Two more cylinders, two more pistons, two more connecting-rods, and an extra length of crank-shaft, and an extra length of base-chamber—and yet to weigh no more. I leave it to your readers to form their own conclusions.

With regard to loss of wall-heat, Mr. Edge in his previous letter admitted that the 6-cylinder was not so efficient as a 4-cylinder engine. As he has again admitted this, there is nothing further for me to say.

When, however, he seriously suggests that a 6-cylinder engine is a guarantee as to freedom from mechanical repairs, I would reply that no 6-cylinder car has yet proved in open competition that such is the case.

Petrol consumption.—Mr. Cecil Edge's *ex parte* statement on this point is interesting but not very reliable. I have heard of 6-cylinder cars which have been incapable of running a greater distance than from 8 to 10 miles on a gallon of petrol. These cars have not been 40-h.p., but of much less horse power.

I am sorry that Mr. Edge should have allowed the discussion on this matter to develop into a personal challenge as between the cars he sells and those in which I am interested. I certainly did not enter into this discussion with the idea of advertising my own cars, in which respect I may perhaps differ from Mr. Edge. My idea was to endeavour to thrash out the merits between 4 and 6-cylinder motors. As, however, Mr. Edge has challenged me, I have much pleasure in accepting his challenge with some slight modification.

In the first place it would obviously be unfair to test the 40-h.p. 6-cylinder Napier against a 40-h.p. De Dietrich, because the 40-h.p. De Dietrich is much larger and more powerful than the 40-h.p. Napier, and obviously a more powerful engine should consume proportionately more petrol.

Again, a road test would be of little use to judge the respective merits of the two types; in fact, any road test for consumption of petrol alone, without speed and power being taken into consideration, is, as Mr. Edge is well aware, worthless from an ordinary user's point of view. It simply means that the car is driven up hill and allowed to roll down every slope with the engine cut out, and as this is not the way a car is driven in the ordinary course of events, such a test is misleading. At the same time, if this is the sort of test Mr. Edge prefers I am, on my part, quite willing.

The chassis or car, however, I propose to accept Mr. Edge's challenge with, would be one of the new 40-h.p. Crossleys, which is approximately in actual horse-power the same as the 6-cylinder Napier. This would give us an excellent standard to judge the respective merits of the two types of engines.

I think also that I would be prepared to state that the condition of the tyres on the Crossley at the conclusion of the run will compare most favourably with those fitted to the 6-cylinder Napier. By all means let there be a test on these lines. I would suggest during the month of February, when I can spare a 40-h.p. Crossley chassis for the purpose.

In view of the discussion having developed into a personal one, I do not propose troubling your readers further, but I would certainly be very interested to learn what other authorities have to say on the respective merits of the 4 and 6-cylinder engines, and express a hope that the test which Mr. Edge has suggested may be arranged.

Yours faithfully,

Dec. 2nd.

CHAS. JARROTT.

SPRING WHEELS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—My attention has been called to a letter from Mr. Verdon Roe which appeared in your columns on the subject of Spring Wheels. Mr. Verdon Roe appears to have convinced himself that the movement of the wheel relative to the axle causes a change of gearing and, consequently, a loss of speed. If it were true that the eccentricity of the axle really makes the wheel momentarily smaller, then it would be possible to prove beyond question that the constant eccentricity of the axle of most spring wheels must result in a gain of speed instead of a loss. The sprocket-wheel does not change in size, and this may be considered as one arm of a lever. The normal size of the radius of the wheel, with the axle concentric, may be taken as the other arm. If the axle sinks, as Mr. Verdon Roe puts it, two inches, this arm, which is working on the ground, becomes two inches shorter, while the sprocket-wheel arm remains the same. Consequently, the engine-power on the sprocket arm must be more effective on the ground, or, in other words, the engine-power will find less resistance to motion. The engine will, therefore, work faster, causing the sprocket-wheel to make more revolutions. But the sprocket-wheel cannot turn without causing the whole wheel to turn also. If the sprocket-wheel makes more revolutions, therefore, we must have greater speed for the same power.

I may add that this argument is not mine, but was sent to me with drawings of a spring wheel, and was used as the advantage claimed because the axle was always considerably eccentric. I may be duller than other people, but it took me quite a considerable time to discover the flaw in the reasoning, which, of course, is incorrect. The explanation of the flaw in this reasoning will at the same time meet Mr. Verdon Roe's criticism. With regard to Mr. Verdon Roe's remarks as to the correct place for springs, namely, between the axle and the body, and not between the rim and the hub, he states it so positively that I feel sure he must have studied the subject very closely. As I take it, the effect of an obstacle only one inch high meeting the periphery of a wheel diameter would be as five horizontally backwards to five vertically upwards. The carriage springs can work only vertically and thus absorb the force represented by fourteen, leaving only one act as a dead shock on the vehicle. A properly-constructed wheel can absorb both the backward and vertical component force of a shock. Besides this the function of a spring is more to do with the running of a car than I have space to enter into here.

Yours faithfully,

Dec. 2nd.

CLIFFORD HALLÉ.

THE "Vanguard" motor omnibus tour, which was announced to take place through France to the Riviera, has, it is reported, been indefinitely postponed.

No less than 51,322 people went on board "Napier Major" at the recent Olympia Show to inspect this remarkably fine sea-going motor boat. The record number of visitors in any single hour was 681

Royal Automobilists.—Not least among the advantages of being a reigning monarch may be reckoned the circumstances that those who enjoy this enviable position can have as many motor cars as they wish for. It is noticeable to what an extent the Crowned Heads of Europe have availed themselves of their opportunities in this respect. Not only has King Edward already a large number of cars, but his stud will be considerably augmented when the new garage which is under construction at Buckingham Palace is completed. The German Emperor possesses a larger number, it is said, of automobiles than any other reigning monarch, and he has recently added at one swoop a batch of seven to his collection. The Kings of Italy, Belgium, Spain, and Portugal are all great enthusiasts of the motor car and each are providing themselves with a fine collection. The same may be said of the Czar of Russia, and the King of Greece, while the Khedive of Egypt, the Shah of Persia, and the Sultan of Morocco are reckoned amongst motor enthusiasts. The Prince of Wales, too, as we have recorded, has added to his collection a 35-h.p. Daimler car of the 1906 type.

THE town of Klatan, which, we believe, is in the Austro-Hungarian Empire, is inhabited by a particularly lazy and artful bull, which, when driven by the local butchers in the direction of the slaughterhouse, lay down on the road on his back, and stolidly refused to budge. No persuasion of the familiar kind would induce him to rise, so when Count Alexander Kolowrat was seen approaching on his motor bicycle, a deputation of butchers rushed out to meet him, and suggested that if he would ride past the recumbent bull at full speed, the terror which his motor cycle would doubtless inspire might galvanise the quadruped on to his feet. The Count performed the operation, and the explosions of the exhaust, unmuffled for the occasion, as he whizzed past the bull produced the desired effect. The reclining one rolled over, got up, and at once took to his heels. Count Kolowrat then held a reception of the butchers, who expressed their hearty gratitude and cheered him as he continued his journey.

AT OLYMPIA.—A three-seated Napier Landulette with a new type of body by Mulliner and Co., which isolates the driver and allows a comfortable third seat to be arranged inside the carriage.

AT OLYMPIA.—A large touring car exhibited by the Maudslay Motor Company. It has seating capacity for five passengers in the carriage.

A FURTHER development of the notion of approaching the South Pole by motor car is attributed—we purposely refrain from using the word “credited”—to a Belgian adventurer, who bears the appropriate name (if he really does bear it) of Arctowski (pronounced Arctoffski). He proposes to put his motor car on skates (or ski) for travelling over the ice. If he ever gets in this way to the South Pole, he will be entitled to add the prefix, “ant,” to his patronymic, and dub himself Antarcowski. But, in the meantime, we rather fancy his suggestion is just a little bit off-ski.

SINCE writing the above, we have learnt that M. (Ant)Arctowski is continuing to develop his ideas for getting to the Antarctic Pole, and “calculates” that, with a motor car such as he proposes to have built, 100 miles a day would be quite easy work on the ice of the Antarctic Continent. The motor car is to be a sort of mixture of automobile and sledge. It is to have a sledge runner which will take most of the load, and thick wheels a foot wide, covered with leather instead of rubber, with thick wedge-shaped nails projecting from their circumference. The car is obviously intended, therefore, to run upon the runner and be driven by the nail-embellished wheels, the pressure on the wheels being varied by raising or lowering the runner. Automobiles have been made, we believe, in the United States and Canada to go on snow and ice by some such means as this, and given a good surface, we have no doubt that M. Arctowski's method might produce locomotion. He seems to be of the opinion (having been there, it is stated, before) that from the points which you land on the Antarctic Continent, to quite near the Pole, are enormous stretches of *smooth* snow and ice. Certainly Captain Scott's experiences were quite different. There was very little smoothness about it, and the crevasses were frequent and tremend-

ous, while in places enormous changes of level were encountered. That is the reason why, when dealing with the subject above, we took a non-serious view of M. Arctowski's proposals. We do not feel sure that his more recent suggestions really necessitate a change of view.

THE idea of building motor cars, not merely to run over ice and snow, but of reaching the South Pole by this means, is said to have found a supporter in Mr. Bruce. He intends to carry on experiments with motor cars designed in accordance with his ideas probably on Ben Nevis or in Norway, the general design of the sledge being an arrangement mounted on runners with wheels specially designed “to give the tractive power of dogs' feet.” Precisely what the tractive power of dogs' feet may be is a question on which experts will probably differ, and they will probably differ more as to the form of wheel which should be adopted to obtain that result. The present suggestion is that leather tyres with cross-ribs should be employed, while springs are to be used “to accommodate the runners to the inequalities of the ice.”

THE Hon. Mr. Lamb, T.C.S., having been posted to duties outside the Presidency, has resigned the Presidency of the Bombay Motor Union, and the office has been accepted by Major-General Greenfield, Commanding the Bombay District.

A SCHEME is in course of being completed for supplying farm and dairy produce direct from a producer in Essex to the consumer in London by means of motor wagons. A meeting was convened this week with this object under the chairmanship of Viscount Deerpur, and the details of the scheme are to be gone into and fully considered shortly. Under the proposed plan, purchasing and collecting depôts are to be established at Ongar, Dunmow, Braintree, and Chelmsford, and the motor vehicles will serve certain districts in London, which will be gradually extended.

AT OLYMPIA.—The Six-Cylinder Rolls-Royce Pullman Limousine, which has seating capacity for seven passengers, and is fitted with electric light, telegraph, and every convenience for luxurious travelling by road.

Session of Parliament to authorise the establishment of a service of motor 'buses.

On Saturday, the first purely Metropolitan Motor Fire Station was opened in London in Red Lion Street, Wapping. The equipment consists of a motor fire engine, and motor combination comprising a first-aid machine and a fire escape, these being manned by an officer and seven firemen.

In spite of the enormous buildings now nearing completion of Argyll Motors, Limited, at Alexandria, near Glasgow, the directors have already decided to further extend these works, the plans which, to this end, are already in hand providing for an expansion to almost double their present extent. The scheme of the buildings as originally laid down was so arranged as to render any addition to the works at any time an easy matter, the manufacturing shops being built at parallel lines running at right angles to the administration building. Thus any one of these buildings can be extended to any desired length, within the limits of the ground, without disturbing

the regular routine of the workmen in any way. The shops, as at present nearing completion, have an average length of about 600 feet, and it is to these that the new extensions are to be added. Even then the directors will not be hampered for further building, as the ground which they have already acquired permits of any of their shops being enlarged to about three times their present length. At the Olympia Show, we learn from the Company, orders were taken for over 500 cars. Such practical evidence of the vitality of the business, therefore, they consider as fully justifying their policy of further expansion.

One of the latest De Dion Cars fitted with handsome Limousine body. It is provided with a 24-h.p. four-cylinder engine, placed under the new De Dion bonnet, has a single-disc-clutch and sliding-spur-wheel gear, giving four speeds and a "reverse." A propeller-shaft transmits the power to the differential casing, and the road-wheels, which run on a stationary axle, are driven direct by cardan shafts on the well-known De Dion principle.

Driving Certificates.—The Automobile Club has been holding examinations for the purpose of granting certificates for car driving and mechanical proficiency at Poole, Southsea, Worthing, and Canterbury, as the result of which examinations 24 candidates have been awarded the former distinction and 15 have received a certificate for mechanical proficiency. The names of these candidates and the places where they were examined are as follows:—

Poole.—Driving Certificate: Arthur Douch, Robert Banwell, W. G. Matthews, Frederick Coles, James Difley. Mechanical Proficiency: W. G. Mantell, Cedric French, Frederick Coles.

Southsea.—Driving: P. H. Samways, W. J. Barton, H. A. Hensley, N. C. S. Rose, J. C. Jarvis, L. M. Steele, A. H. Terry, Sergt. Cannon, R.M.A. Mechanical: P. H. Samways, Sergt. Kelly, R.M.A., Sergt. W. Cannon, R.M.A., Sergt. H. J. Neal, R.M.A., Gunner A. Smith, R.M.A., Gunner R. J. Welch, R.M.A.

Worthing.—Driving: J. E. Stroud, C. Carver, P. J. Turtle. Mechanical: M. F. Mievill, A. E. Bradshaw, J. E. Stroud, C. Carver, P. J. Turtle.

Canterbury. Driving: F. G. Wyborn, W. Mugeridge, Oswald Fuller, A. M. Boulter, L. V. Cann, W. J. Cann, A. H. Ellis, Mrs. M. F. Phelps. Mechanical: L. V. Cann, W. J. Cann.

It has been decided by the Sheffield Automobile Club that the Motor Show at Sheffield is not to be held by the club, but the club will grant its patronage to a privately organised exhibition in the town for next year.

On Friday of this week Sir William Preece, K.C.B., F.R.S., delivered the prizes at the Annual Prize Distribution and Conversazione at the Northampton Institute, Clerkenwell, E.C.

THE Todmorden Town Council have determined to promote a Bill in the next

The above photograph shows Mr. John Hargreaves' 80-h.p. Gordon-Bennett Napier Racer in the innocent garb of a very fine ordinary touring vehicle. This is the same vehicle which Mr. Hargreaves drove in racing trim in the last Eliminating Race held in the Isle of Man, when the car and its driver were selected as reserves for England in the actual Gordon-Bennett Race.

LEGAL INTELLIGENCE.

The Straker Steam Vehicle Company (Limited) v. Lehwess.—Judgment was given in this case by Mr. Swinfen Eady in the Chancery Division on Thursday in last week. In this action, the plaintiffs sought for an injunction against the defendant to enforce an agreement dated October 28th, 1904, and also applied for an injunction to restrain him from selling in England or in English Colonies any motor vehicles manufactured by Messrs. Bussing and Co., of Brunswick, while they further sought to restrain him from "representing or stating that the plaintiff Company is not entitled to all rights and interest in relation to the sale or purchase in England or the English Colonies of the motor vehicles aforesaid." The action arose out of arrangements made between Dr. Lehwess and Messrs. Bussing, of Brunswick, in the first instance, by which Dr. Lehwess was to act as their agent in this country. In pursuance with these arrangements, the defendant, Dr. Lehwess, contracted both with Messrs. Bussing and the Straker Company for the latter to place certain orders for chassis with the former, transferring the benefit of his agreement with Messrs. Bussing to the Straker Company for a consideration to himself of £1,000. Subsequently, the defendant, it was alleged, endeavoured to interfere with the business by threatening Messrs. Bussing, and attempting to induce them to believe that the Straker Company were not acting fairly with them. At the same time it was stated that he had got together an English syndicate to whom, from the Judge's summing up, it would seem he endeavoured to procure the transference of the agreement which he had already assigned to the Straker Company. Mr. Justice Swinfen Eady used very strong remarks in his judgment, referring to letters which the defendant had written to Messrs. Bussing in the following terms:—

"The defendant was not called to give evidence and his counsel said he would not attempt to justify them, and perhaps it will be sufficient if I say that the letters are quite unjustifiable, because they indicate a course of dishonest and fraudulent conduct which it is impossible to justify."

and added,

"What took place was this. The defendant, having arranged for this sale under which he was to receive £1,000, then proceeded, as far as he could, to take away from the purchasers and to secure to himself the benefit of what had been sold."

His Lordship finally granted the injunction asked for, ordered the defendant to pay the costs of the action, and allowed enquiry as to damages, the costs of the enquiry being reserved.

THE Crown Agents for the Colonies require for immediate shipment to Ceylon a petrol motor car from 20 to 30-h.p. (to seat six persons), capable of travelling at 20 to 25 miles per hour on the flat, and of climbing a maximum continuous gradient of 1 in 20. A gear-driven car, with roof suitable for carrying light luggage, is preferred, and it must be new or in perfect order. Full particulars in writing should at once be forwarded to the Crown Agents for the Colonies, Whitehall Gardens, S.W.

COMMERCIAL POINTS.

MESSRS. GAUTHIER AND Co., of 60, Great Marlborough Street, inform us that their representatives will be at the Paris Salon in constant attendance at the Malicet and Blin, Bassée-Michel, and Ballot and Co's. Stands, and they will be pleased to see any members of the trade there, whether they come to purchase or not.

MR. F. F. WELLINGTON, representing the British Automobile Commercial Syndicate, Limited, will be at the Paris Show on the stand of Messrs. Spyker Brothers, of Holland, where a representative of the firm will also be present to afford information to English visitors to the Exhibition.

MR. GLYNN, of the Gaulois Tyres, Limited, advises us that he will be in attendance during the Paris Salon, at the stand of Messrs. Bergougnan and Cie., manufacturers of the Gaulois tyres.

THE Austin Motor Company, of Longbridge Works, Northfield, near Birmingham, are now in a position to undertake repairs of all makes of cars, as they have installed a department especially for this purpose. Petrol, lubricating oils and spare parts for any make of car will be obtainable and a stock of tyres of all sizes will be kept, and accumulators can at any time be charged. As the works are situated on the main Bristol road close to Birmingham, the address of the Austin Motor Company should be made careful note of by automobilists.

THE Ryknield Engine Company, of Burton-on-Trent, have issued a circular in regard to certain misleading paragraphs which have recently appeared in some of the trade papers giving the impression that the business of the Company is about to be discontinued. In their communication they state the true facts of the case as follows:— "Ever since the Tourist Trophy Race, in which the 15-h.p. Ryknield car was one out of two or three cars which did an absolute non-stop run, negotiations have been proceeding with a view to strengthening the financial position of the business, and so making it possible to take full advantage of the demand arising from the good performances of our cars both in public trials and in the hands of private users. You will understand while these negotiations were in progress it was extremely difficult for us to make a statement regarding the position. We are pleased to inform you that our arrangements are now practically completed, and to facilitate this re-arrangement the Ryknield Engine Company, Limited, goes into voluntary liquidation, and the whole business will be taken over by a new company now in course of formation, which will probably be known as the Ryknield Motor Company. In the meantime, the business will be carried on without intermission, and we hope to have the first of a new type of 20-h.p. 4-cylinder car on the road by the end of this year."

LADY ALWYNNE COMPTON has just ordered a second Crossley car of the 1906 model, as a result of her pleasing experience with her first Crossley. The new car will be of the *laudalette* type, the carriage body having been entrusted to Messrs. Hooper and Co.

A MOTOR ROAD SWEEPER AND SPRINKLER.—There has recently arrived in London a machine for watering and sweeping the streets which is propelled by a petrol engine. It is the invention of M. Muller de Cardévar who has already made trials in Paris which are said to have been so satisfactory that the capabilities of the machine may be favourably compared with those of six sweepers and sprinklers drawn by horses. The brush, which is chain-driven, can be raised from the ground when not required, and the vehicle can then proceed on its top speed to its next scene of operations. Immediately in front of the brush is a water sprinkler, and additional sprinklers also project behind. In use, the machine is said to travel at about 5½ m.p.h.

NEW ISSUES.

City and Suburban Motor Cab Company.—The prospectus of this company was issued last week, the whole of the share capital of £100,000, in £1 shares, being offered for subscription. The cabs to be employed are those known as the "Unic," manufactured by Messrs. Georges Richard and Co. The preliminary expenses in this company are to be paid for by the sum of £15,000 in cash, in the event of £30,000 being subscribed. If a less sum is subscribed, the payment is to be 50 per cent. of the cash subscribed, the balance being paid in shares. The directors are Sir Henry Seton Karr, C.M.G., M.P., Colonel Anstey, Messrs. Godfrey C. Isaacs, J. O. Lawson Johnston, J. Cumming Macdonald, M.P., and C. Wyndham Quin.

The Associated Omnibus Company, Limited.—An issue of 50,000 5 per cent. first mortgage debenture stock at par was made this week by this company. The purposes of the issue are for considerably increasing the motor bus services, which the company have already found of a profitable nature, from the number which they have had running on various routes worked by them.

The Automobile Cab Company Limited.—The share capital, £100,000 in £1 shares, of this Company has been offered for subscription this week, the Company being formed for the purpose of placing motor cabs on the London streets, each of which will be fitted with a taximeter. The vehicles which will be chiefly employed are those supplied by the Central Motor Car Company,

Limited. The Directors are Sir James T. Ritchie, Bart., J.P., Messrs. H. E. Wootten, B. H. Morgan, C.E., and S. A. Chambers. The business manager is Mr. Samuel Michaels, until recently President of the London Cab Drivers' Union. The preliminary expenses are placed at £7,000, for which sum Dewhurst & Co., Limited, undertake all such expenses down to the first general allotment of shares. This amount is besides underwriting commissions.

NEW COMPANIES REGISTERED.

Automobile Cab Company (Limited), 7 and 8, Walbrook, E.C.—Capital, £100,000 in £1 shares. Object, to adopt an agreement with the Central Motor Car Company Limited.

Motor Traction Company, 1905 (Limited), 14, Great Winchester Street, E.C.—Capital, £60,000 in £1 shares. Object, to acquire part of the assets of the Motor Traction Company, Limited.

Rapid Road Transit Company (Limited).—Capital, £10,000 in 9,000 shares of £1 each, and 20,000 shares of 1s. each.

"Rocket" Motor Omnibus Syndicate (Limited), 79, Salisbury House, London Wall, E.C.—Capital, £6,000 in £1 shares. First directors: W. S. Leefe, F. W. T. Thorp, H. Hiscott, and E. H. Saunders.

Street Motors Limited, 76, York Street, Westminster.—Capital, £2,000 in £1 shares. Object, to carry on the business of manufacturers of and dealers in motors, motor cabs, &c.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

admixture of air and gas or vapour entering the carburettor before passing to the engine cylinder. There are three figures. Fig. 1 is a vertical central section; *a* is the body of the carburettor, *b* the passage leading therefrom to the engine, *c* the usual float-chamber containing the oil or spirit to be fed to the carburettor, *d* the regulating float therein, and *e* the passage leading the oil or spirit from the chamber, *c*, to the carburettor. In order to allow the engine to be worked economically at high speeds the plug or nozzle, *f*, in the carburettor, *a*, is made of comparatively large diameter, and surrounded by an enclosed annular air-chamber, *g*. Passages, *h*, are formed in this body of the plug or nozzle, *f*, which conduct air from this annular chamber, *g*, to points more or less closely surrounding the aperture, *i*, of the nozzle, *j*, which admits the spray of oil or spirit, and projects it against a baffle or against a heated tube, *k*, for example. The oil or spirit spray and the air are thereby mixed in the proportions suited for starting the engine. In the mixing-chamber above the plug or nozzle, *l*, and adapted to slide more or less air-tight therein, is an open-ended vessel, *m*, of cylindrical or other convenient shape, the lower part of which is arranged to close more or less the annular air-chamber and form a valve, *n*, which rests upon a valve seat, *o*, formed on the outer upper edge of the plug or nozzle, *f*. This open-ended vessel, *m*, may be furnished with a stem, *p*, which passes through the cover, *q*, of the carburettor casing, *a*, whereby the vessel, *m*, may be raised or lowered as required, a spring resistance, *r*, being provided if desired. This vessel, *m*, may be actuated by the suction of the piston in the engine cylinder by hand or by the governor.—November 15th, 1905.

of one is made to transmit motion to the other by two or more friction wheels connecting the two cones. These friction-wheels, *e*, are arranged so that they may be moved axially so as to connect either the two smaller ends of the cones or the two larger ends of the cones, *c* and *d*, or any intermediate parts, the two cones being forced together by a spring, *f*, and kept apart by the friction-wheel, *e*, thus obtaining the necessary pressure between the surfaces of the cones and friction-wheels. The position of the friction-wheels is varied by an arrangement of collars, *g*, sliding on fixed axes, *h*, and actuated by interior screws, *i*, which move nuts, *j*. These nuts are provided with keys which pass through slots in fixed axes, *g*, and engage the key-way in *j*, the wheels, *e*, running loose upon the collars, *g*, and the screws, *i*, being actuated by bevel gear, *k*, and *l*, with a separate small pulley, *m*, which is made in one piece with *k* (outside the main pulley), and is actuated by a chain, *n*, hanging down within easy reach of the operator. The shafts, *g*, are fitted in a frame, *r* and *s*, fixed by set screws to the collar, *p*, and a rod or rods, *q*, *q*, is fixed to this collar, the rod or rods being attached to the ceiling or wall, thus preventing the frame, *r* and *s*, from moving. The pulley, *h*, is fitted with its boss on a loose collar, *u*, on the shaft, *a*. If the shaft, *a*, is driven it carries with it the cone, *c*, and this cone through the friction-wheels or rollers, *e*, communicates motion to the outer cone, *d*, which carries the pulley, *h*, and according to the position of the friction-wheels or

PASSING EVENTS.

Mr. Justice Grantham at Full Charge.

WE are becoming more and more doubtful whether Mr. Justice Grantham is really to be taken seriously. His remarks at the trial of Charles Guillemard, on which we commented last week, were exceedingly funny to listen to and read for anyone but the unfortunate automobilists who were fired at. But we assumed it was Mr. Justice Grantham's first attempt to be funny in a serious case and did not expect an early repetition of similar injudicious remarks—at any rate for some time. His charge to the Grand Jury, however, in the case of what one might popularly term the "cyclist scout perjury trial," but which was officially known as *Rex v. W. T. Whittington Jones*, was really more than a joke. The case was one of those very questionable indictments in which a Grand Jury would have been fully justified in throwing out the bill, and this it would seem—judging by his charge to the Grand Jury—was precisely what his Lordship was afraid of. Said Mr. Justice Grantham:—

The police very properly did all they could to see that the speed limit should not be exceeded, and in this they would have the sympathy of the general public. Of late there had been a new development of the warfare between the police and motorists by the introduction of cyclist "scouts," men whose sole object appeared to be to assist in evading the law by going about the country warning motorists who were infringing the statutes. It was not surprising that the police resented this practice, and tried to catch the law-breakers, *and so they took proceedings against this defendant, who they alleged had sworn falsely in order to get a motorist off who was driving too fast.* They knew how constantly people committed perjury in courts of justice, and when a serious case arose it was quite right that proceedings should be taken against the offender.

Mr. Justice Grantham's tacit admission should be noted in the passage which we have italicised, that the prosecution was instituted mainly, if not solely, because the police were annoyed.

Creating Prejudice.

OF course that is not the worst of the matter. Even where the Grand Jury finds a true bill, as they do in the majority of cases, an alleged culprit has a fair trial before an ordinary jury subsequently. Ordinary jurors, however, are liable to prejudice, and this is particularly so in country districts in cases where the automobile is concerned. It is not for a moment to be supposed that the remarks of the Judge in charging the Grand Jury pass unnoted by the ordinary jury. Of course, a judge summing up the case is in a different position altogether. He has heard the evidence. But these remarks were made by this extraordinary Judge before any evidence had been tendered. If similar observations had been made by a newspaper we know what would have happened. Under the circumstances it is a triumph for good sterling British common sense and the spirit of fair play that the accused was ultimately acquitted.

A Campaign of Intimidation.

HAD the prosecution for perjury succeeded, it would, of course, have been the first step in a regular system of persecution of the employees of the Automobile Association and all others who dared to attempt to counteract the trappists' methods. In fact, it would have meant that before long to swear against a policeman would have involved the danger of hard labour or penal servitude. It would have meant nothing less, for there was no serious evidence against Mr. Jones but that of the interested policemen. If a prosecution of this kind succeeded in one case, the police would soon have

become the absolute masters of the destiny of everybody, for soon no one would dare to swear against them. Fortunately, the decision the jury arrived at has put a summary stop to any such intended campaign, and we do not anticipate many attempts to repeat it. Considering Superintendent Marks' record, considering the things that he has been compelled himself to admit under cross-examination in the witness-box in automobile cases, and considering the apparently vindictive action attending the arrest, we are not at all certain that Mr. Jones would not have a very good prospect of success in an action for malicious prosecution. In any case, we should like to see the Automobile Association try it, for even if they failed, it would warn police officials that they cannot bring these sort of charges with absolute impunity.

A View Confirmed by the Judge.

If anybody imagines that this is an exaggeration of the case, that this was only an exceptional occurrence, and that prosecutions for perjury in such cases would not have become general, we would refer him to the remarks made by Mr. Justice Grantham, which we have quoted above. He there says that the objects of a cyclist scout appear "to be to assist in evading the law . . . and that it was not surprising that the police resented this practice . . . so they took proceedings against this defendant." There is accordingly all the more reason to congratulate the Automobile Association on Mr. Jones's acquittal. But *nemo me impune lacessit* is an excellent motto, and the Automobile Association would certainly make their position safer in future, and ensure that malicious charges of perjury of this kind are not repeated, by instituting, as we have suggested, an action for malicious prosecution.

Malicious Prosecution?

THE Automobile Association (and in this matter perhaps the Motor Union may back them up) ought, therefore, seriously to consider whether this is not a case in which the statute against malicious prosecutions might be satisfactorily invoked. The opinion of Mr. Gill, at any rate, was pretty clear. He pointed out in open court that

"the proceedings could and should have been taken by summons, inasmuch as Jones could have been found, and if a warrant had been necessary it should have been executed at a time when he could at once have been brought before a magistrate and bail obtained."

Mr. Gill characterised these proceedings as "a gross outrage and scandal." These are strong words from so distinguished a barrister, and one with such an extensive experience of criminal cases! It really seems a pity that the people who have done what they could to blast the whole future of a harmless member of society should be allowed to get off scot-free.

An "Alice-through-the-Looking-glass" Summing Up.

THE summing up of Mr. Justice Grantham in the actual trial was, if possible, more prejudiced against the automobile movement generally and the unfortunate prisoner Jones in particular, than his "charge" to (we had almost said *at*) the Grand Jury. But it had the saving merit of being one of the most muddled pronouncements we have ever heard from the Bench, and such a general mix-up that Mr. Gill had on several occasions to set his Lordship right as regards the actual facts. It would have been highly funny if it had not been so prejudiced and virulent, and if it had not been a question of hard labour

or penal servitude for a young man who had never done any harm to anyone, and on whose character there was not a stain. Fortunately the jury were not so prejudiced, and they evidently rated the Judge's remarks at their true value, for they promptly returned a verdict of "Not Guilty."

It is impossible, after perusing the verbatim report of the learned Judge's remarks, part of which we give on another page, not to be reminded of two classical passages in the works of Lewis Carroll, which in case any of our readers may not call them to mind, we append herewith:—

"If you did not sign it," said the King, "that only makes the matter worse. You must have meant some mischief or else you would have signed your name like an honest man."—"Alice in Wonderland."

"Nobody walks slower than you do," said the King. "I am sure I do my best," said the messenger. "If nobody walked faster than you do," said the King, "he would have been here first."—"Alice through the Looking Glass."

A Duty which the Automobile Association should assume.

IN referring to the proceedings of the Automobile Association, we learn with some regret that several well-meaning people are thinking, or at any rate arguing, that the tendency of the Association's campaign will be to give the reckless driver a new lease of life, in fact, to encourage the "road-hog" at the expense of the "hedge-hog." They allege that if the police-trap is to be universally out-generalled, out-manœuvred, and generally rendered ineffective by "masking" it with cyclist scouts, there will be nothing to keep the really reckless driver in subjection. A more telling indictment of police tactics could hardly be imagined than these assertions would provide if they were true, but we are glad to think, all the same, that they are not true, for we understand that the Association has made a practice up to the present of invariably discouraging reckless driving wherever they encounter it, and that they will be even more careful in future on this point than they have been in the past. They will be able to do so with the greatest ease. All that is necessary is that it should be generally known that motorists who are driving with obvious recklessness will not be "warned" by the Association's scouts, and that bad cases will be reported by them to the Automobile Club. The suppression of the reckless driver is of almost greater importance to and more devoutly desired by all good motorists even than by the general public. The future of the movement largely depends on his suppression, and as the Automobile Association has the future of the movement thoroughly at heart, it may be relied upon to do all it can to prevent abuse of the high roads.

Further Testimonials to the Motor 'Bus.

UNDOUBTEDLY the finest testimonial that the motor 'bus has received is provided by the two letters—one from the London Road Car Company, and the other from the Associated Omnibus Companies—which have recently appeared in the London Press, designed to reassure their shareholders, and to stop the panic which the directors must evidently regard as imminent, or they would hardly have taken so extraordinary a course as to publish a communication designed to convince their shareholders that everything is for the best, with the best of all possible omnibus and road car companies. Both the Road Car Company, the General Omnibus Company, Messrs. Tilling and Co., and the Associated

Omnibus Companies protest with much vigour that they are not neglecting the motor 'bus, and that on the contrary they will be having any number of them running in a short space of time. Alas! it was not always thus with them! We fear that their tendency was to ignore the motor 'bus until the motor 'bus could no longer be ignored. We have urged them often enough, and other papers have urged them, to adopt the motor 'bus while it was a newcomer; but this they persistently refused to do in act if not in word. Now, instead of leading they are following the lead of others, and meanwhile a golden (or copper) harvest is being reaped by the progressive and enterprising companies who have been first in the field.

Danger Ahead.

THE value of this harvest, however, seems likely to have a result that may be dangerous to the industry. Attempts are again being made to utilise the popular appreciation of the motor 'bus for company promoting purposes on the old bad lines, which has invariably spelt disaster for any industry to which they have been applied. None can be more anxious than we are to see motor omnibuses entirely supersede horse-drawn vehicles, not only on account of the enormous advantage and convenience of that great improvement in street traffic, but for economic and sanitary reasons as well. But we would *again* caution the public, as we have cautioned them in the past, to be very chary of investing in promotions which, on the face of them, are obviously designed to secure promoters' profits in the first place, without much care as to what happens to the companies so promoted afterwards. If such operations are carried out on at all a large scale, it will mean a repetition of the destruction of confidence in legitimate motor concerns generally, from which the industry has suffered in all departments for so many years, and from which it is only now just beginning to recover. Of operations of this kind, this Journal was one of the most vigorous opponents in the past, and much as we desire to see the general motorisation of London 'bus traffic at an early date, we would prefer to see it postponed for a considerable period rather than that the general welfare of the industry should be imperilled by reckless promotion of motor 'bus companies of the kind with which there appears some danger to believe we are at present threatened.

The extent to which the question is becoming one of considerable financial magnitude is being clearly recognised in the City, and an important article adopting the same general attitude to the situation as we have taken up has been published by the *Financial Times*. The appearance of such an article in an independent and financial authority of such standing is so great that we make no apology for reproducing a résumé of it on another page, the figures contained in which are highly instructive.

Isle of Man Motor Trials.—Lord Raglan, at Tuesday's meeting of the House of Keys, announced that the Automobile Club had forwarded him a cheque for £250 towards the up-keep of the Isle of Man roads, in token of the appreciation and consideration they had received in being allowed to run the Gordon-Bennett trials and the Tourist Trophy race in the Island in May and September last.

PARIS SALON 1905.

ON the 8th December, President Loubet opened the Eighth International Automobile Salon at the Grand Palais. The Show remains open until the 24th of the month.

There was at one time no small amount of discussion in English motoring circles as to the advisability of holding our own exhibition prior to that in Paris, but if any doubt remained on that point it should at least be cleared away now that the Paris Salon has shown the public what it has to offer. The importance of the English market to France has always been fully realised, and it was, of course, justly taken for granted that those French manufacturers who were directly interested in it, would see that their new models were quite ready for the Olympia Show. This, with but few exceptions, has proved to be the case, and the natural consequence

It is not surprising that these considerations have borne themselves in upon the majority, and the fact that the A.C.G.B.I. were unable to organise a combined minimum party of thirty in connection for even one special train is, therefore, a matter upon which further comment is needless, for it is obviously—when taken into consideration with the big parties which were made up in former years—a most convincing sign of the times. Those who may have crossed over from England to visit the Show in a non-professional capacity must have found but little to reward them if they were anxious to see new tendencies in design or radical novelties. From a spectacular point of view, of course, the Grand Palais in the Champ Élysées offers attractions which are in many ways superior to anything which

Mons. G. Rives. President Loubet. Mons. Trouillot.

THE PARIS SALON.—President Loubet leaves the Exhibition after paying a most exhaustive visit, during which he evinced personal interest in the new models of practically every exhibitor of note. The President—who arrived at 10 o'clock to open the Salon—was attended by a distinguished party. In the above photograph he is accompanied by M. Gustave Rives, President of the Organisation Committee (on the left), and M. Trouillot, Minister of Commerce (on the right).

is that the Paris Salon has, from the English point of view, lost almost its entire importance. No foreign car at the present day has any real interest to the English buyer until it is established in England, for the days are long since past when English motorists bought their cars direct in France, and now that the majority of the really first-class firms have agents or branches here, it can be assumed that the Olympia Exhibition offered the pick of the world's automobile productions. Of these exhibited productions, too, it may be said, in parenthesis, that the English-made vehicles rank second to none either in sound construction or high-class finish, and the time has now gone for ever when the English automobile engineer may seek any material benefits from a preliminary glance—such as has hitherto been afforded by the Paris Salon—at the latest creations of his Continental *confrères*.

England has to show, and its unique situation lends itself to an extensive scheme of decoration which the A.C. de France have carried out with their usual lavish disregard of cost.

At first sight it may not appear to be important, this gay illumination in the Avenue Nicholas II. and the other approaches to the Palace, but it gives just that air of being *en fête* which is required to attract the Parisian, and it popularises the automobile, in consequence, among the masses, who cannot afford to use them. It has, too, the effect of turning the Salon into a local attraction, which is not altogether desirable, for in the early evening the crowd is so dense that it is practically impossible to move about and, to judge by appearances, the majority do not mean business. This, however, is

evidently recognised by the Administration, for they close the doors at 7 o'clock each evening. For anyone who wishes to "do" the Show thoroughly, the Grand Palais is a fatiguing place, for it has innumerable galleries, some parallel to each other and others at right angles, so that it is impossible to take them all in a general walk round. As at last year's exhibition, too, quite a number of exhibits entirely unconnected with motoring have been allowed to take space, and the hapless visitor is assailed with offers of perfumery and toys when he is expecting to find the latest thing in magnetos and sparking-plugs. On the ground floor, there is the Cupole d'Autin, and the galleries adjoining it, which the visitor is apt to miss, as also Gallery "A," immediately to the right of the main entrance, where the Societe Paris Automobile this year show one of the 6-cylinder

congratulations to the Administration, for the two combined make a great improvement.

Last year, it will be remembered, the heavy vehicles and boats were removed to the Serres de la Ville, which is situated in the Cours la Reine, directly opposite to one of the entrances to the Grand Palais. It is the same this year also, and, in addition, the Aeronautical section—which previously was in the gallery, round the Cupole d'Autin—has been allowed to join them. At the present moment, the majority of the exhibits in the Serres de la Ville are hopelessly incomplete, and down in the *sous sol* men are at work in actually constructing the floors and seats of some of the boats which will eventually be on show. It is nothing short of amazing, however, how quickly an exhibition can be made complete, and what appears to be chaos in the evening has a habit of

THE PARIS SALON.—View looking down the Grand Nef just before the official opening. In the foreground painters are seen at work on various chassis, and this general finishing off proceeded throughout the day. Generally speaking, however, the exhibits were wonderfully complete. Although not conspicuous for their individual merit, the tout ensemble of the various "signs" has at once a magnificent and artistic effect.

Napiers, for which they have secured the French agency. Inside, the decorations and illuminations are, as usual, on a magnificent scale, but it is difficult to say if they are better than before, because they have always been so very elaborate. Under the glass dome there is the wonderful electric sun, which has, for some time now, formed the culminating feature in the general scheme of illumination. On one point, at least, there is a marked improvement, the aisles are now covered with matting instead of the horrible loose gravel which has characterised them in the past and it is thus for the first time possible to walk about the Exhibition in moderate comfort. At intervals, down the centre of the main aisle, are the same pillar-box-like warming stoves, but these, owing to the mildness of the weather, have not yet been called upon to taint the atmosphere beyond its usual closeness—and on this also we would offer our

appearing most orderly by the following morning. It may possibly be the same in the Serres de la Ville, although the heavy nature of some of the exhibits evidently militates against quick work.

English and American Exhibitors.

One of the most gratifying features of this year's show is the importance of the English exhibits, and it is a matter for considerable congratulation to find British cars taking their stand in this way in the capital of the French industry. With the notable exception of the Napier chassis, which are shown by San Giorgia (of Genova) as well as by the Societe Paris Automobile, all the English cars have good positions in the Grand Nef among the best Continental cars. These include those of the Wolseley and Siddeley Company, Argyll Company, Humber, Limited, and the Star Engineering Company,

THE PARIS SALON.—A Gallia Electric Vehicle constructed for a perfumery firm in the Galleries St. Martin. Designed in the Louis XV. style, with artistically painted panels, this little voiturette forms a most striking exhibit, and it gives, besides, some idea as to how far a definite style is applicable to automobile carriage work.

while the "British" light car is exhibited under the Cupole d'Antin. There would have been, in addition, an exhibit by C. S. Rolls and Co., had they not been so unfortunate as to secure an "impossible" position in the ballot, causing them in consequence not to exhibit at all. It was hardly to be expected that any of these firms would have anything new so soon after the Olympia Show, and generally speaking this is the case, although the Wolseley and Siddeley Company are arranging to exhibit one of their new 25-h.p. chassis, which was not ready in time for Olympia; this had not, up to the time of writing, arrived at the stand, however, owing to some delay in transit. Several cars and chassis were on view, however, including that little 6-h.p. model, with the vertical engine and propeller-shaft driven live-axle, which was one of the features of this stall at the last Salon, but was not exhibited at Olympia. No chassis is on view at the Argyll Company's stall, but they are showing two complete cars instead. All the latest improvements on these vehicles have been very thoroughly dealt with in our recent special article, so it will not be necessary to refer in detail to them here. In Paris, too, these cars are likely to become well known for they are now in the hands of those who are bringing their many excellent features before the notice of Continental motorists. Similarly situated with regard to the French market is the Humber Company, who exhibited, in addition to complete cars, one of the new 16-20-h.p. chassis. At Olympia, it will be remembered, they did not show a chassis on account of the small space available, although they were well represented in this

respect at the Stanley Show. As, however, we have in course of preparation a special article on the latest Humber chassis, it will not be necessary to refer further to it here except to say that it is of simple and up-to-date construction, and has been well designed to meet the requirements of those who want a powerful and reliable car of extremely moderate price. In this respect it can hardly fail to appeal to a very large section of the French public also, for at the present Salon the equivalent to what might be termed the English Tourist Trophy type of car is not very conspicuous.

In addition to the English cars, there are the two well-known American cars, the "Oldsmobile" and the

THE PARIS SALON.—One of the Argyll single landaulette cars exhibited at the Salon. The car is of 16-20-h.p., and has from the opening day been attracting a considerable amount of attention from the visitors to the Exhibition.

THE PARIS SALON.—Side view of one of the new Richard-Brasier chassis. This is one of the very few well-known firms who did not exhibit their new models at Olympia. Engine and gear-box are carried on a long tubular underframe and the side members of the mainframe are perfectly straight when viewed from above. They are also pressed complete with flanges to which the chain-sprocket brackets can be fixed, one of these being visible above. Three-quarter elliptic springs support the frame at the rear. Combined with the main clutch, which is of the leather cone type, there is a positive clutch formed by a set of projecting, cylindrical pins which engage in corresponding oval slots and so prevent the clutch from slipping. This positive clutch is held in engagement by quite a weak spring and it is practically impossible to touch the pedal without disengaging it. A very neat adjustment is provided for the clutch-pedal itself by which its position can be suited to the requirements of the driver.

Cadillac, the former represented by its Paris agents, and the latter being shown from headquarters in the States. The Columbia car is in evidence, as is also another American exhibit, under the name of the American Locomotive Company, who are constructing Berliet cars under licence.

Continental-Touring Cars.

At a French Exhibition it is, of course, from the French cars that most is expected, and certainly those of the well-known manufacturers are well worthy of inspection at this year's Paris Salon. Practically without exception, however, the exhibits have all been on view at Olympia. Messrs. De Dietrich come, of course, under this category, and although their splendid little new model—the 12-15-h.p. chassis—is now shown in France for the first time, Messrs. Jarrott and Letts have already made it familiar in England, and a fully illustrated description of it has appeared in our columns. The new 40-h.p. chassis is also on view again, and creates as much sensation as did its prototype of the previous year. Messrs. Panhard have an excellent exhibit, too, although they do not show any of the 6-cylinder models which Messrs. J. E. Hutton introduced at Olympia this year. Neither is there anything fresh on the Mercedes and De Dion stands beyond what has already been exhibited in England. Messrs. Richard Brasier were one of the very few well-known firms who failed to put in an appearance at Olympia, and consequently their new chassis are now features of especial interest to English motorists. With the exception of the smallest model, 15-h.p., all are chain-driven. Constructed of pressed steel, the sides of the main frame are quite straight when viewed

from above, and they are pressed with flanges to which the chain-sprocket-brackets can be directly fixed. Three-quarter elliptic springs are employed at the rear, and these lie outside the frame. Both engine and gear are supported by a long tubular underframe, and the engine itself is of quite a new design, which is very conspicuous for its neat appearance. All the valves are arranged on the same side, but the low-tension igniters are on the opposite side, and are operated in an unusual manner by an exposed horizontal shaft alongside them. The main clutch is of the leather-faced cone type, but it has a supplementary positive clutch which enters after the cone-clutch is engaged. This supplementary clutch is

THE PARIS SALON.—View of the new Richard-Brasier Engine, showing the horizontal shaft, A, which operates the igniters by means of small face cams. The shaft, A, is driven by bevel gearing from a vertical shaft, A', and provision is made for automatically retarding the ignition when starting, although normally the timing is fixed.

THE PARIS SALON.—View of the supplementary brake, A, on the new Mors Chassis. The brake-drum is fixed to the differential countershaft and independently operated by foot through the rod, A¹. It is anchored at A² to the cross-bar, A³, which is hinged to the frame at one end only. Passing around the cross-bar, A³, is a link, B¹, which connects the side brake operating-rod to its cross-bar, B, and it is against this link that the cross-bar, A³, abuts when the foot brake is applied to the drum, A. The idea is that the momentum of the vehicle can in this way be used for helping the application of the rear-brakes because the torsion of the drum, A, on its band is all transmitted, indirectly, to them.

formed by a series of pins which engage in slots in the fly-wheel boss.

Many new features were also evident on the Peugeot models, notably the Mercedes type of change-speed-gear and the internal expanding-brakes, of which there are four—two on the hubs, one on the countershaft, and one immediately behind the gear-box, which is separate from the differential casing. A ratchet-sprag is fitted to the brake-drum on the differential countershaft, but this is not inter-connected with the reverse. This year, a new model having a 50-h.p. engine has been added to the list of standard cars. The 1906 Westinghouse model is in the main similar in design to that shown by them—as a new car-building firm—at the 1904-5 Salon, when they were awarded a gold medal, but several important improvements have now been introduced. It has a 4-cylinder engine of 30-h.p. that runs at a normal speed of 1,000 revs. per. min., a disc-clutch, ball-bearings throughout the transmission, two independent foot-brakes as well as the hand-brake, and side chains to drive the road-wheels. Of other well-known French cars, those such as the Clement and the Gladiator were shown in London, as was the new 14-22-h.p. Belgian Germain, while the new Dutch Spyker chassis with its dustless frame has not, up to the time of writing, put in an appearance, and its place on the ingenious revolving-stage erected for its benefit is at present occupied by a less interesting substitute.

Italian cars—of which the best known in this country is the Fiat—have developed so rapidly of late that they have this year assumed a proportion in numbers such as enables them to be referred to collectively under their nationality. It happens that practically all the Italian cars are being exhibited at the Salon, there being the Fiat, Bianchi, Itala, Florentia, Isotta Fraschini, Rapid, and Züst, and, considered as a whole, it must be admitted that they form a series of sound engineering jobs which are worthy, individually and collectively, of

that nation's engineering reputation, and of that of the firms who made them. Although most of these firms started building cars somewhat late in the day, yet they have been content to bring their established engineering skill to bear in the careful, but not too literal, copying of the best practice of the day. The result has been a series of valuable contributions to the list of first-class cars. Of the names mentioned, the Fiat has, of course, long since become a household word in this country among those who speak of first-class cars, the Itala was introduced last year by the Fabri Automobile Company, and the Bianchi is now in the hands of Messrs. Straker and MacConnell, who exhibited it at Olympia. Of

the others, two—the Rapid and the Züst—have not been shown before, but the former will in all probability be

THE PARIS SALON.—The Mors Automatic Starting Device. When starting the engine the driver has only to draw forward the handle, A², give a stroke or two of the pump, A, and switch on the battery ignition—the engine should then start, for the first operation has opened up communication between the cylinders and the pump and the second action on the part of the driver has charged them with carburetted air. On the dashboard is a small tank, A¹, called the "dynamogene," which acts as the carburettor. In this illustration, part of the new Mors clutch is visible. Cast on the fly-wheel is a projecting rib, B, which forms a drum, and this is gripped on its external face by an ordinary metallic brake-band. One of the operating levers, B¹—which revolve—is also visible; they are worked by a simple sliding cone on the main shaft.

THE PARIS SALON.—Side view of the new Serpollet Chassis, which is now constructed with a single chain drive to a live-rear-axle. Most important of the new features, however, is the engine, which is now double-acting. In front, under the bonnet is the boiler, which together with the "system" generally, remains the same as it was last year.

brought to this country by the Fabri Automobile Company at an early date. There is very little difference between the various cars, but the Itala, Rapid, and Florentia are of the live axle type, whereas the others are chain driven.

New Cars at the Salon.

This year's Salon is most disappointing in its production of new cars. There are new cars, it is true, but hardly any are conspicuous for originality, and comparatively few for their good workmanship, other than those which have been already referred to as such under other headings. Most of them have engines of the ordinary 4-cylinder type, with the cylinders cast in pairs and the valves arranged on opposite sides. Some—such as the Underberg, Bail, and Sage—have wood frames stiffened with flitch plates, while the others—like the Argus, Buire, Rebour, Saurer, Desgouttes, and Delaugere and Clayette—have the more orthodox pressed steel variety.

On the De Salvert chassis, the tubular casings enclosing the halves of the live-axle are set obliquely to the differential casing in order to splay the wheels. In this respect it is somewhat like the Aries which made a feature of the same principle last year, but the essential difference between them lies in the fact that the Aries employs a stationary axle for supporting the wheels and the differential casing, whereas the De Salvert is constructed in a similar manner to ordinary shaft-driven live-axle cars. Some form of petrol-electric

vehicle is generally fated to be numbered among the new cars at the Salon, and this year there is the L'Auto Mixte. There is, however, nothing very special about it as a system, for it merely employs a shunt-wound dynamo which does duty for a change-speed-gear. Beneath the driver's seat is a battery of accumulators which is charged by the dynamo, which can of course be used as a motor when required either for increasing the speed of the car or for helping it up-hill. It is, also, the only means of reversing. A magnetic main clutch is introduced, and there is an electro-magnetic control on the throttle-valve.

Steam Cars.

Three new cars have been added to the not very lengthy list of steam vehicles already on the market, they are the Weyber and Richmond, Fidélia, and L'Auto Vapeur. None of them appears to embody anything especially

THE PARIS SALON.—View of the new Serpollet Engine, showing the duplicate set of valves for the double-acting cylinders, which are operated from the same cam-shaft. One row of valves controls the admission and exhaust to the one side of the pistons and the other set to the other side, so that an impulse is obtained every stroke. By the side of the engine are two long tubes, A, through which the steam is passed before taking it to the honeycomb radiator. Inside these tubes are others through which the feed-water to the boiler is passed, so that this in turn becomes heated in advance.

THE PARIS SALON.—View of the steam engine on the new Weyber and Richemond Car. It has four horizontal cylinders arranged in pairs on either side of a spur pinion fixed to the centre of the crank-shaft. Combined with the crank-chamber is the casing around the differential which is driven by the spur-wheel on the engine crank-shaft. The rear wheels are driven by side chains. In front, under the bonnet, is a semi-flash boiler of the Serpollet type.

original or ingenious, for while the first two employ a Serpollet-type boiler with its own engine, the last uses a 4-cylinder engine of the Serpollet old type with its own boiler. In the Weyber and Richemond car there is a 4-cylinder horizontal engine arranged transversely in the frame, and it drives a differential-countershaft direct by spur-gearing. The rear road-wheels are thus chain driven. In front, under the bonnet, is the boiler, and at one side of the frame is the steam donkey-pump for feeding the water and fuel; from the limited information at present available we do not, however, gather that there is any automatic control on either vehicle, although both can be regulated by the driver, from the dash. The Serpollet-type boiler on the Fidélia car is placed at the rear of the chassis and there is a 4-cylinder vertical engine in front under the bonnet. In appearance this engine is very similar to a small petrol engine, its cylinders are separate and the valves are arranged in a similar manner on opposite sides. It is, in fact, only the slender appearance of the cylinders which draws attention to the engine at first sight. A cardan-shaft drives the live-rear-axle, but a feature of the system is the introduction of a leather cone-clutch in order to allow the engine to run free when required. All the pumps are driven by eccentrics from the engine crank-shaft, and the main-clutch allows the engine to be used, so to speak, as a donkey pump, for it requires very little steam to drive the engine when disengaged from the propeller-shaft, and it only requires a few strokes of the hand-pump to start it from cold. With the exception of a cut-off valve on the feed water (which operates at about 900 lbs. per square inch) the system is not automatic, the driver regulating the fuel and water by hand and momentarily making use of the clutch when the steam supply runs low. In the Auto Vapeur car, the boiler is a simple multi-tubular arrangement provided with a superheater beneath it. The 4-cylinder engine is

arranged horizontally in the centre of the frame, with its cylinders opposed in pairs; it drives the live-rear-axle through a cardan-shaft.

It is around the latest Serpollet car, however, that most interest centres this year, for the changes that have been made to it are even more radical than they were last year. The cardan-driven live-axle has been abandoned for one which is driven by a single chain, and the horizontal engine—which is placed longitudinally in the frame—now has two double-acting cylinders instead of four single-acting ones. In appearance, the engine is as compact as before, for the valves are very neatly arranged in two rows, one below the other; they are of the same mushroom type as hitherto, and are operated by one cam-shaft.

No alteration has taken place in the system as a whole, so far as it affects the control of the car; its leading features were described, it will be remembered, in connection with the last Salon, when they were originally introduced. There is one important addition, however, in the shape of a feed-water-heater, consisting of a compact multi-tubular device through which the exhaust steam and the feed-water pass simultaneously; it has, too, a further advantage, inasmuch as it allows the honeycomb condenser to be of a smaller size than would otherwise be necessary. The boiler is placed in front of the dash, under a bonnet which is similar to those used on petrol cars, but is distinctive by reason of a perforated portion which ventilates it.

Another well-known steam car is the Chaboche, but this, as exhibited at the Salon, remains practically the same as last year, except in a few minor details.

Among such a gathering of steam vehicles we were sorry not to see the White, for without so well known and popular a vehicle the section to which it belongs must necessarily be incomplete.

Last week we published a photograph of an interesting 3-seated Napier landaulette, in which an entirely new type of body was shown which isolated the driver and, at the same time allowed a comfortable third seat to be arranged inside the carriage. Messrs. Mulliner, whose design this is, must be gratified to learn that it so took the fancy of M. Charron, of the Paris firm of Charron, Girardot, and Voigt, that he made an offer for the body from Messrs. S. F. Edge, Ltd., for the express purpose of showing it in the Paris Salon, now in full swing, on one of the C.G.V. carriages, a point in favour of British workmanship, which Mr. Edge so appreciated as to be induced, under the circumstances, to accede to M. Charron's wishes.

(To be continued.)

HIGH-TENSION MAGNETO IGNITION.—PART XIX.

THE LACOSTE SYSTEM.

Now that high-tension magnetos are no longer a novelty, in themselves, the chief interest in any new model centres mostly in those features which the manufacturer has considered worthy of special development. The Lacoste High-Tension Magneto has been constructed more especially with a view to strength—

dentally, too, the low-tension mechanism is mounted at one end of that half-speed shaft which drives the high-tension distributor, so the armature spindle, which usually carries this portion, is less encumbered, and allows more room for the "timing" gear.

Electrically, the Lacoste system is not peculiar, neither has it been specially designed for alternate use with battery ignition, although it is, nevertheless, quite possible for it to be so used, and the Lacoste Company have made a high-tension switch which is designed for the purpose. On a new model, moreover, which is now being made at the works, we noticed that special modifications are being made in this direction.

The Magnets.

The magnets, G, are similar in most respects to those commonly employed on magnetos, being of the compound horse-shoe type and made up of six separate elements secured together by common cast-iron pole-pieces, G², to which they are attached by screws. The complete construction is mounted on an aluminium base-plate, G¹, so that it may be easily attached in place on the car. Instead of being perfectly parallel, the pole-pieces are tapered at each end in such a way that the air gap between them and the armature is less at the centre than at the ends. This is an important feature in the design of the machine, and it is done in order to direct all the magnetism towards the centre part of the armature core *before*, instead of *after*, it leaves the magnets.

The Armature.

The armature is rather larger than usual, because an additional amount of insulation has been provided, in order to reduce the chances of electrical breakdown under even abnormal conditions of use. As usual, the centre part of the core, A, is laminated, but instead of forming the armature-cheeks, or side plates, A², of cast-iron, they are, in this instance, made of brass. Each pair of cheeks is cast in one piece with a flange joining two of its ends, and this flange, which is a

FIG. 1.—The Lacoste High-Tension Magneto. View of the complete apparatus showing the manner in which everything is enclosed under aluminium covers.

electrically as well as mechanically—and protection from damp and dirt. Thus all exposed parts are of aluminium—casings being provided where the object itself cannot be constructed of this metal—and, for the purpose of rendering the electrical equipment less liable to break down, all the high-tension contacts are embedded in solid insulating material, so that only the necessary plug connections are in any way exposed.

With the same idea of strength, the armature is made larger than usual in order to allow ample room for more insulation, and there is another interesting feature in its construction, from a mechanical point of view, which will be explained presently.

Being of the real high-tension type, both high and low-tension coils are wound on the armature itself, but in order to render the circuits quite distinct, the high and low-tension mechanisms are situated at opposite ends of the machine. Inci-

FIG. 2.—The Lacoste High-Tension Magneto. View of the Magneto after removing the magnets, which are shown separately on the left. The duplicate Brushes, C¹, collect the Low-Tension current from the Slip Ring, C¹.

"shuttle-shaped" plate, is riveted up against the sides of the core, A, as is clearly indicated in Fig. 3.

This form of construction is, of course, adopted in order to make the armature as rigid as possible, but the use of brass as a material for the cheeks, A², is, nevertheless, a curious departure from orthodox practice. The elimination of solid masses of iron from the core—which cause Foucault currents and interfere with quick reversals of magnetism—is the principal advantage obtained, but this would be accompanied by an increased tendency for the lines of force at each end of the pole-pieces to stray unguided through the non-magnetic brass,

two. The low-tension current is collected from the slip-ring, C¹, by two brushes, C², mounted in brush-holders, C³. These brush-holders form plug-fittings in the aluminium plate previously mentioned, which rests across the top of the pole-pieces, G², (Fig. 2). Although there are two brushes, C², it will be noticed that both rest on the same slip-ring, C¹, and are, besides, electrically connected together above, so as to be virtually one brush. These brushes are made from different materials, one of brass and the other of carbon, this arrangement being found necessary on account of the high peripheral velocity of the ring, C¹, and the

FIG. 3.—The Lacoste High-Tension Magneto. Views of the component parts. On the extreme left is the box enclosing the Timing Gear; the Spur Wheels for driving the Spindle, D², are mounted on the Bearing Plate, M, which carries the Low-Tension gear—but, being enclosed, are not visible. Above the Armature, which is in the centre, is the Condenser, F, and all the High-Tension gear is mounted on the far side of the Bearing Plate, M¹.

were not the pole-pieces themselves tapered in the manner and for the purpose already explained.

Brass end-plates, B², are fixed to the core, at both ends, in the usual way, and these carry the halves of the armature spindle, B and B¹. Both primary and secondary windings are wound over the centre part of the core and one end of each is earthed to it. The live end of the primary winding is connected to an insulated slip-ring, C¹, mounted on the periphery of one of the end-plates, B², while the live end of the secondary winding is carried through the armature-spindle, B¹, where it terminates in a contact-knob, D¹.

The Low-Tension Gear.

Unlike most magnetos of the real high-tension type, the low-tension mechanism in this case is not mounted about the armature-spindle, but about the distributor spindle instead. Being driven at half the usual speed, it is necessary for the contact-breaker cam, B⁴, to be provided with four projections instead of

advisability of lubricating the brass brush—such lubrication being afforded in this case by the soft carbon.

These brushes are directly connected by means of a flexible wire to the terminal, C¹², which in turn is connected, through a switch, to the terminal, C¹³ (Fig. 5). This latter terminal forms part of the small bracket which carries the adjustment-screw, C⁷, of the contact-breaker, C². When the contacts are closed, therefore, the armature primary winding is short circuited on itself.

All the low-tension gear proper is mounted on a circular brass plate which is covered by a neat aluminium case. A detailed view of this mechanism is given in Fig. 6, which shows all its important parts and renders their action obvious. The cam, B⁴, is mounted on the distributor-spindle, D², but the gear-wheels driving this member will be referred to in connection with the high-tension gear.

(To be continued.)

EVIDENTLY the tram and rail service from Ealing leaves something to be desired, for an enterprising firm are running a service of motor 'buses through the principal shopping thoroughfares of Ealing to Broadway Station. A penny fare is to be charged for the whole

distance of nearly two miles. Similar enterprise is being displayed at Chiswick, where, it is reported, a private motor omnibus company has been formed by the householders of Grove Park to run between that spot and Turnham Green.

THE NEW ARROL-JOHNSTON PETROL CARS.—PART V.

expanding brake. It will be noticed that they occupy a remarkably small amount of room in all, and yet each is of sound construction in itself.

Beginning with the universal joint—the function of which is to connect the propeller-shaft, H^9 , with the short bevel-pinion shaft, M —it will be seen that the forked end, L , is somewhat similar to that (H^7), at the forward end of the same propeller-shaft, but that its radial pins are provided with square guide-blocks, L^1 . The radial pins give the needed hinge-motion in one plane. In the other plane, however, the required freedom of action is obtained in a very different manner, for, inside the forging, L , is a spherical socket—formed by two hardened steel sleeves—that fits around the central “ball,” L^2 . The ball itself is mounted on the main casting, M^1 , which is securely fixed to the shaft, M .

For giving the necessary telescopic motion, the guide-blocks, L^1 , are carried between projecting arms—these arms being a part of a special fitting, L^3 —and the “ball,” L^2 , is also rendered free to slide upon its sleeve, M^1 . The special fitting, L^3 , is mounted, as seen, between the external casing, M^2 , and the casting, M^1 , those two parts being bolted together in such a way as to leave it free to revolve independently; thus it is that the propeller-shaft really drives the fitting, L^3 , but has no direct mechanical connection with the shaft, M . Between the fitting, L^3 , and the casing,

Fig. 21.—Three views of the Arrol-Johnston Live-rear-axle, fitted with the “Spring-drive,” Universal-Joint and Expanding Brakes, which are amongst the special features of these new cars.

The Live-Axle and “Spring-Drive.”

FOR the sake of convenience, these two important parts of the new Arrol-Johnston cars will be considered together, and they are, indeed, illustrated conjointly in our photographs and drawings. Fig. 21 includes three views of the axle—one being taken from the end, one from above, and the other obliquely from in front. In Fig. 22, the various parts constituting the axle and the “spring-drive” are shown grouped together on a table, and the propeller-shaft, H^9 , is also included in this group. The line drawings in Fig. 23 show the precise construction and arrangement of every part, the larger section taking the axle with the spring-drive in place upon it, and the other drawings giving additional sections of the spring-drive.

Most ingeniously arranged, in conjunction with the spring-drive, are no less than three other functional devices, for not only is there the universal-joint for the propeller-shaft, but provision is made for the telescopic motion of that shaft, and there is, in addition, the foot-operated

Fig. 22.—View showing the various parts of the Arrol-Johnston Live-rear-axle, Spring-drive, Universal-jointed Propeller-shaft, and Internal Expanding Brakes.

M², however, the four springs, M⁴, are introduced, these springs pressing up against the external projections of the former, and against the internally projecting lugs, M³, that form a part of the latter. Two of these springs transmit the power to the shaft, M, when the car is being driven forwards, and the other two come into operation when "reversing."

The whole mechanism is rendered oil-tight, in much the same way as the universal joint at the forward end of the propeller-shaft, by the aluminium cover, L², and a

points to notice are that the upper half of the central casing can be taken off without much trouble, and that the road-wheels run on the roller-bearings, N⁴, *outside* the axle-tubes. Other strong features are that the short shaft, M, is supported by substantial bearings on both sides of its bevel-pinion, M², and that it is quite impossible for the road-wheels to come off even though the driving-shafts, N, should break. This latter point is ensured by the ring, N⁵, behind the wheel, the ring fitting over a flange, as seen in Fig. 23; between the ring and the flange is a leather washer to retain the oil

Fig. 23.—Sectional drawings of the Arrol-Johnston Live-rear-axle, and of the Combined Universal Joint, Spring Drive and Foot-operated Brake.

leather stocking (not shown in our illustrations). Also bolted to the casting, M¹, in such a manner that it can readily be removed, is the brake-drum, M⁶, inside which are the expanding brake-shoes, P, with their operating mechanism. The brake-shoes are mounted upon the castings forming the axle-casting, and the brake is of precisely similar construction to those at each end of the axle.

Coming now to the axle itself, the most important

(To be concluded.)

ANOTHER example has come to our notice of the extent to which the underhand and irritating tactics adopted by the police are recoiling on the institutions with which they are connected, is provided by some correspondence which has recently taken place between Sir Archibald Macdonald, Bart., J.P., and Mr. George Cave. Mr. George Cave wrote to Sir Archibald asking

Adjustable ball-thrust bearings are arranged on each side of the differential, the outer shell, N¹, of which is made in two parts so as to hold the planet-spider, N², between them. Long plain bearings support the shell, N¹, inside the axle-tubes, N³, and similar bearings carry the live-shafts, N, inside the shell-casings. In Figs. 21 and 22, the torque-rod, N⁶, is visible, and it will, of course, be understood that the side radius-rods are attached direct to the spring-brackets.

for a subscription to the Surrey Police Sanatorium, to which Sir Archibald replied that it would have given him great pleasure to send a cheque for £100 for that institution, but regretted that he was quite unable to entertain the request owing to the constant and systematic persecution of motorists by the police within the districts which would chiefly be benefited thereby.

THE 1906 WINTON CARS.

(Continued from page 1532.)

The Change-Speed-Gear.

ALL other features of Winton cars, with the exception, perhaps, of the pneumatic control, must be considered as minor characteristics to the Winton gear. In principle,

run free until brought into use by being gripped between two clutches (disc and cone), which revolve on either side of it. Just how these clutches are arranged and operated is most clearly indicated in Fig. 11, although Fig. 12 gives a good general view of the interior of the gear-box after removing the top half. Connected

to the engine is the driving-shaft, L, which runs through the box to the other end. On this shaft, either directly or indirectly according to the design employed, is the short tubular shaft, N, which carries the shaft, L, where it passes through the box to its far end.

On the other side, is the lay-shaft, M, which is employed for low-speed and reverse, but runs idly while the top-gear is in use. Keyed to the driving-shaft, L, are two steel pinions, L¹ and L². Of these, the pinion, L², meshes directly with a wheel, M¹, on the lay shaft to give the low-speed, while the other drives an intermediate pinion (not shown), and thus, indirectly, the wheel, M¹—which is also free on the lay-shaft—to give the reverse. These wheels, M¹ and M⁴, are each placed between friction clutches, M², M³, and M⁵, M⁶, respectively, but normally the clutches do not touch the wheels, their clearance being ensured by the action of small helical springs interposed between them. In order to bring these clutches into engagement, pivoted dogs, P¹, P², are operated by a sliding collar, P³, from one of the side levers. On the collar, P³, is a double conical wedge which lifts the long ends of the dogs and so forces the short ends against the outer surface of the disc-clutch,

Fig. 10.—The 25-h.p. Winton Car.—View showing the Gear-box in place on the Chassis, also the mechanical force pump lubricator on the dash. Also visible are the Brake-pedal, S, and the Accelerator-pedal which operates on the Air-valve, B¹.

our readers are already familiar with it, but as the details of its construction have necessarily been somewhat modified on the live-axle models, we again give a description of its action and parts. There are only two speeds and a reverse, and each gear is introduced simply by pushing gently forwards or pulling gently backwards one of two long levers arranged at the driver's right hand. There is no main clutch, and consequently no clutch pedal to be depressed as a preliminary to gear changing; but each gear has an individual clutch of its own, which is engaged or disengaged by the operation of the side levers. Each pair of wheels in the gear-box is always in mesh, but only the steel pinion of each train is permanently keyed to its shaft, the wheel driven by it—which is of bronze—being allowed to

which in turn moves along the shaft, until the gear-wheel, which it carries with it, is forced against the cone-clutch on the other side. As the cone-clutch cannot move sideways, the wheel is, consequently, gripped fast,

Fig. 11.—The 25-h.p. Winton Car. Sectional drawing Gear-box and Live-rear-axle, showing how the individual are arranged for operating each speed, and illustrating end-thrust is eliminated once any clutch is engaged

Fig. 12.—The 25-h.p. Winton Car. View of the interior of the Gear-box showing the clutch operating mechanism for introducing each speed. In this view (on the right) one of the small springs which keeps the jaw-coupling behind the fly-wheel from chattering is also clearly visible.

and is then capable of transmitting power to the lay-shaft, because both the disc and the cone-clutches are mounted on keys. From the lay-shaft to the driven-shaft, N, the power is transmitted through the wheels, M' and N', which are always fixed to their respective shafts. For the high speed, the lay-shaft is not employed at all, a direct-through-drive being available by coupling the shaft, N, to the shaft, L, through the cone-clutches, L³, L⁴, and N¹ and N². In just the same way as the low-speed and reverse are introduced, so is the high-speed engaged, although some slight modifications have been made for constructional convenience. Thus the dogs, P², do not press directly on to the back of the clutch, L³, but on to a plate, P³, which in turn transmits the pressure through loose pins, P⁴, carried by the wheel, L². This method has been adopted to save space in the gear-box, and a glance at Fig. 11 will show how much larger the box would have to be, were the sleeve, P¹, placed on the other side of the wheel, L², merely in order that the dogs might operate more directly upon the clutch.

One of the most ingenious features of the Winton gear is the manner in which end thrusts have been avoided, for it is only just at the moment when the gear is being engaged that there is any pressure along the shafts, and this is entirely eliminated when the gear is fully "in," owing to the fact that the cone-clutch is in each case forced against a collar on its own shaft, and that the dogs cannot, if properly adjusted, react on the sliding sleeve. It is in order to eliminate end thrust, too, that the supplementary cone, L⁴, is employed for the high speed, but obviously this could not very well have been placed inside the box without adding complications. Apart from the adjustment in the gear-operating-rods

themselves, there is a very simple adjustment, inside the gear-box, for resetting the dogs. They are for this purpose mounted on a threaded sleeve which is locked to the gear-shaft by set screws, P⁹, and it is, therefore, a simple matter to release these screws and move the dogs closer up to their respective clutches whenever that may be necessary. In order to avoid damaging the thread, the set screws tighten up on to soft brass plugs interposed between them and the shaft.

There is no intermediate shaft between the main gear-shaft, L, and the engine on account of their proximity, which enables them to be directly coupled. In order to allow a slight self-alignment to take place between them, however, a simple double-jaw coupling is introduced, and it will be noticed, in Figs. 11 and 12, that the loose intermediate piece between the jaws is prevented from chattering through being secured by two springs.

The Brakes.

Band-brakes are employed throughout, on the Winton cars, and, contrary to usual practice, it is the foot-pedal which operates those on the hubs of the rear-wheels; that immediately behind the gear-box is operated by pushing forward the "high-speed" gear-lever. Bronze brake-bands are used, and it is their springiness alone which allows them to grip the drums. For operating the rear-brakes, the foot-pedal is connected to the centre of a transverse bar passing across behind the back-axle. This bar operates the toggle-levers which draw in the brake-bands, and it is owing to the springiness of so long a rod that these brakes are compensated.

Remarkable Claim for Road Damage.—A claim has been made by the local authority near Bristol against the Western Road Carrying Company for "extraordinary traffic damage" to the roads, alleged to have been caused by the company's motors. We are not quite certain whether this is the first case of the kind which has been brought, but we are under the impression that it is. In any case, the subject is one of very great importance to all users and manufacturers of

heavy commercial vehicles. On the result of the action no doubt will depend whether or not a general attempt will be made to enforce such claims against motor lorry owners. After carefully considering the subject, the Society of Motor Manufacturers and Traders have agreed to make a grant of £50 to assist the Western Road Carrying Company in its defence, one of the many instances of the effective manner in which the Society is looking after the interests of the industry.

A FINANCIAL VIEW OF MOTOR 'BUS PROSPECTS.

WE have consistently and persistently deprecated what we cannot help regarding as the very dangerous attempts being made in certain quarters in the Press to establish the motor 'bus boom on the regular company promoting lines which have done so much harm to other branches of the industry in the past. We have pointed out more than once that motor 'bus companies, though if conducted on business-like lines and on a proper basis, they are likely to prove satisfactorily remunerative, will not probably be the Tom Tiddler's ground which attempts are now being made to induce the investing public to believe they are. It is therefore with considerable satisfaction that we find so independent an authority on financial matters as the *Financial Times* devoting a carefully considered and exhaustive article to the question, of which we reproduce some extracts below.

enough, is shown by the relatively small amount of money which the old horse companies have raised in this connection. Below we record the capital provided :—

CAPITAL PROVIDED BY THE OLD COMPANIES.

Company.	Amount.
	£
Associated Omnibus ...	50,000
London General Omnibus ...	40,000*
London Road Car ...	60,000†
Star Omnibus ...	75,000
Thomas Tilling ...	60,000
	285,000

* Set aside from revenue. † £20,000 only called up.

As regards the profit-earning capacities of motor 'bus undertakings, the *Financial Times*, after observing that most of the prospectuses of the new companies give

Prospectus Estimates.

Omnibus Company.	No. of 'Buses.	Profit per Mile per 'Bus.	Total Profit per Year.	Average Yearly Profit per 'Bus.	Div. on Ord.	Surplus for Administration, Depreciation, Reserve, &c.	Miles Run per Day.	Days Worked per Year.	'Buses held in Reserve.*	Allowance for Depreciation.
		d.	£	£	p.c.	£			p.c.	p.c.
London and District	200	2	45,000	225	10	20,000	90	360	?	20

Motor 'Bus ...	120	2a	39,800a	331	10d	24,800	109	full year	20	20 (?)

a. Allowing for depreciation.

b. 40 double and 40 single-deck omnibuses.

c. For single-deck omnibuses.

d. On £150,000 of capital.

* Of total acquired.

After considering the marked depreciation in the stock of the London General Omnibus Company and the shares of the London Road Car Company, which has been recently chronicled, and which nothing in the condition of London but the advent of the motor 'bus can explain, and pointing out that the great 'bus companies have been most mistaken in not themselves adopting the motor 'bus earlier, the article proceeds as follows :—

While recognising this, however, we cannot but deprecate the rush of new motor 'bus companies into the field. As in the cycle trade and the motor car construction industry, so in this case, the result of such a flood of prospectuses may easily be a weeding-out process which will not prove pleasant to some of the shareholders. The extent to which these promotions have attained during the current year may be judged from the following table :—

Company.	Total Capital.	Issued Capital.		Total Issued Capital.‡
		Pf. Shrs.	Ord. Shrs.	
	£	£	£	£
Automobile Cab. ...	100,000	nil	100,000	100,000
Ct. & Sub. Mot. Cab ...	100,000	nil	100,000	100,000
Lon. and District Motor 'Bus.	*405,000	nil	250,000	255,000
Lon. Motor 'Bus ...	†303,000	200,000	100,000	303,000
Lon. Power 'Bus. ...	200,000	nil	200,000	200,000
Lon. and S.-C. Motor ...	100,000	nil	100,000	100,000
Motor 'Bus ...	*305,000	nil	150,000	155,000
Total ...	1,513,000	200,000	1,000,000	1,213,000

* Including £5,000 deferred shares. † Including £3,000 deferred shares. ‡ Including deferred shares.

Here we have a total capital of over one and a-half millions sterling (of which by far the greater part has been issued) embarked in the exploitation of London by motor omnibuses and cabs. Huge as the traffic of the Metropolis is, one cannot but conclude that the thing is being overdone, especially as further promotions are in the wind. This is the one extreme. The other, of not doing nearly

evidence of the experimental nature which still attaches to these undertakings, points out that so far only two companies, the London Motor Omnibus Company and the London Power Omnibus Company, are in a position to furnish actual results. The statistics of the former company, include the running of 'buses from the beginning of January to the end of October. After allowing for renewals and depreciation, 2d. per mile net profit is put down as the amount earned; though during October they estimate their profit at 3d. per mile. The London Power Company, on the other hand, estimates its net profits at 3½d. per mile without allowing for depreciation, which it calculates at 12 per cent. From the various prospectuses of motor 'bus companies, the above table of costs and profits, &c., has been compiled.

After remarking that with the exception of the two companies referred to above, these estimates are to some extent problematical, while the variation in the estimates of profit earned are distinctly noticeable, our contemporary concludes as follows :—

Needless to say, the solution of these questions, as well as of the probable gross receipts, must determine the financial future of these undertakings, and until they can be ascertained with some approach to accuracy those who invest their money in such ventures are taking a leap almost in the dark. It has also to be remembered that the old horse companies, although they have hitherto been supine, are by no means yet "played out," and are still likely to prove most formidable competitors in the motor 'bus business.

⊗ ⊗ ⊗ ⊗

THE illegitimate use of motor horns—as annoying in Ceylon as at home—has caused the Automobile Club of Ceylon at Colombo to petition all municipalities in the island to consider the desirability of prohibiting the use of motor horns on other than motor vehicles.

THE TOURIST TROPHY REGULATIONS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I quite agree with what Mr. Edge says in his letter to you with reference to steam cars.

It seems to me that the new Tourist Trophy Regulations as they now stand with regard to steam cars are unfair both to petrol and to steam cars. They are unfair to petrol cars because they give steam cars using petrol as a fuel an advantage over petrol cars; they are unfair to steam cars, because they make steam cars using a cheaper fuel than petrol go the same distance on a gallon as steam cars using petrol.

The only just and fair method of settling this question of fuel, to my mind, is to make one fuel—petrol, for instance—the standard or unit; all cars, steam or otherwise, using petrol to go the same number of miles on a gallon; cars using any other sort of fuel to go a less or more number of miles on a gallon, as the price per gallon of their fuel varied with the price of petrol.

I cannot see why the Tourist Trophy Race should not be thrown open to all kinds of cars using any kind of fuel, but it is obviously unfair to make cars using a cheaper fuel go the same number of miles per gallon as cars using a dearer and more dangerous fuel.

The use of a cheap, less dangerous fuel, ought to be encouraged as much as possible, but as the rules of the Tourist Trophy Race now stand, it is more advantageous to use petrol than any other fuel.

Yours faithfully,
J. E. G.

York, Dec. 5th.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I deprecate the use of the correspondence columns of THE AUTOMOTOR JOURNAL by those interested in the motor trade in the discussion of questions which affect their goods. Some members of the trade agree with me on this point, while others are careful that their names, signed to some letter, appear nearly every week in the motor papers.

I certainly should not have entered upon the controversy started by Mr. Claude Johnson had not the Hon. Chas. S. Rolls, who is associated in business with Mr. Johnson, written the letter which you have seen fit to publish on page 1545 of your issue of Dec. 9th. Apparently Mr. Rolls does not think Mr. Johnson sufficiently capable of explaining his use of the word "inefficient," and has come into the lists to defend Mr. Johnson's use of that term as applied to the steam car.

To term the steam car "inefficient" because it will not run 25 miles on one gallon of fuel over such a route as the Tourist Trophy course in the Isle of Man, may possibly be correct, if one wishes to strain a point. The customary use of the word "inefficient," however, is such that to apply that word to some steam cars on the market very naturally gives offence, not only to their manufacturers but to their users, for the sole and very good reason that such steam cars are anything but inefficient.

Were I to use the word "inefficient" in connection with a car which was to compete, or had competed, in the Tourist Trophy Race, I should judge that it would better be applied to a car which was not capable of completing 2 miles out of the 208 miles of the race.

"Inefficient" or "efficient," the "White" cars in next year's Tourist Trophy Race will certainly complete a greater portion of the course than 2 miles of it.

The majority of the correspondents who are dealing with the Tourist Trophy Race lose sight of three cardinal points. These are as follows:—

1. The technical committee of the club, as I understand it, wishes to promote, in promoting the Tourist Trophy Race, a competition wherein, by a limitation of fuel consumption, piston displacement will be so limited that the competing cars will be confined to a limited horse-power, say, for the purpose of argument, 24-h.p.

2. The technical and races committees, as I understand them, wish to find a basis of fuel allowance whereby a steam car will be also limited to, say, 24-h.p., and in doing so, take into consideration the generally admitted fact that a steam car, no matter how efficient, consumes a greater quantity of fuel (regardless of what the price of that fuel may be) per mile, under certain circumstances, than is used by a petrol car.

3. That the question of price has no particular effect on this argument, except in so much as it enables the owner of a steam car to run his car 100 miles for practically the same cost of fuel as a petrol car can run, although a greater quantity of a cheaper class of fuel is used.

If one wishes to find out whether or not the makers of steam cars think that the mere fact that their cars consume more actual bulk of spirit per mile than is consumed by petrol cars needs to be established, I would respectfully refer the inquisitive to the catalogues of the steam car manufacturers.

I wish to close my letter as I began it with an apology for entering these columns with a letter on such a subject, but it is entirely against all reason to expect me, as a steam car manufacturer, to sit quietly by and listen to the cool denunciation of my particular product by those who represent a product which might well be proud of the record which the car that I represent has gained at the hands of the A.C.G.B.F. alone, to say nothing of its record in various other parts of the world, extending over the last five years.

Do let us conduct the automobile trade without denouncing each other's products, and if one wishes to say that a petrol car runs further on a gallon of fuel than a steam car will do let us say so, and not wrap up the statement in a word like "inefficient," which may mean a variety of things; but unless one searches for an excuse to make it do so, could never in fairness be applied to a steam car.

Yours faithfully,

Dec. 8th.

FREDERIC COLEMAN.

POLICE PERSECUTION—AND AN APPEAL.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—We have had a tough and bitter fight, but at last the truth prevailed, and a British jury has expressed its definite opinion of the evidence given by Superintendent Marks and his satellite, Police-Constable Sharp, by accepting our cyclist patrol's testimony in the face of their sworn condemnation.

Our committee recognised that this case had a far-reaching issue, that it menaced the safety of anyone who dared to tell the truth in defence of a motorist. We, therefore, poured money out without a thought other than the collection of overwhelming expert evidence and adequate representation by counsel.

But for this a shameful miscarriage of justice must unquestionably have occurred, and a kind of Spanish Inquisition would have superseded the present County Bench proceedings, which most of us think are awful enough. In these circumstances I put it to you, sir, that we deserve more than mere sympathy or congratulation. Our good work on the road is sadly curtailed by so great a drain upon our financial resources, and this should not be. It need not be if all motorists, in the cause of whom this battle was fought and won, will contribute to its cost. I therefore earnestly beg your valuable influence to the end that both makers and users of motor cars will give freely to our Defence Fund.

Donations or subscriptions will be gratefully acknowledged by the Executive Committee of

Your obedient servants,
THE AUTOMOBILE ASSOCIATION.
STENSON COOKE,
Secretary.

18, Fleet Street, E.C.
Dec 12th.

⊗ ⊗ ⊗ ⊗

A WRITER in the *Daily News* is quite concerned about the 10 per cent. dividend which the London Motor 'Bus Company have recently declared. He seems to think it quite a scandal that a private company should be earning so much money out of catering for public locomotion!

ALL interested in the technical development of the automobile will learn with great regret of the sudden death of Mr. I. M. de Havilland, of Messrs. Legros and Knowles, Limited. Mr. Havilland entered the service of Messrs. Legros and Knowles in April last, and has been the chief designer of their newest types of car, which attracted so much favourable attention at the recent Olympia Exhibition. Mr. de Havilland was an enthusiast for the automobile, and Messrs. Legros and Knowles inform us that his whole heart was in the production of the very best car that could be brought out. About a fortnight ago he fell a victim to a severe attack of influenza, the effects of which were responsible for his death, which occurred on Sunday last. The occurrence is a particularly sad one, as Mr. de Havilland was only twenty-seven years of age, was already in a fine position, with an assured future before him, as the firm which he had served so well had decided to take him into partnership.

THE GUILDFORD PERJURY HUNT—ON WHICH SIDE WAS THE PERJURY? ACQUITTAL OF THE AUTOMOBILE ASSOCIATION'S SCOUT.

SOME few weeks ago we referred to the case of the Automobile Association's cyclist scout Jones, who, on a charge of perjury, was arrested by the police on a Saturday afternoon, when there was no possibility of bringing him before a magistrate and liberating him on bail, so that, though it was well known where he lived, and his address in the hands of the police, he was kept in durance vile till the following Monday. The last act of this drama was played out at the Guildford Assizes last week, when Mr. Jones was finally brought to trial on this charge and—acquitted. We refer editorially to this case in our present number, more particularly to the amazing remarks made by Mr. Justice

Grantham in reference to it, when charging the Grand Jury. We are able below to reproduce verbatim some of the Judge's most confused, remarkable, and entertaining utterances, but in order that the situation may be fully grasped, we must recapitulate the circumstances out of which the charge of perjury against Mr. Jones arose. On the 23rd of September last Mr. Jones was performing his functions as one of the scouts of the Automobile Association on the Fairmile, near Esher, where a notorious trap of Superintendent Marks has been for months organised. Into this trap, just on Mr. Jones's arrival, entered Mr. Johnson, and as Mr. Johnson passed along the measured stretch of road, Mr. Jones rode on his bicycle behind his car. From the pace at which he was himself riding, he was convinced that Mr. Johnson could not have exceeded the 20-mile limit, and he subsequently communicated his name to Mr. Johnson as that of a witness who was willing to give evidence in his defence. When Mr. Johnson's case was brought before the Kingston magistrates, Mr. Jones gave the evidence in question, viz., that he was riding behind the car at the time, but in spite of this Mr. Johnson was "duly" convicted. This occurred on the 19th of October, and it was not till Thursday, the 9th of November, that Superintendent Marks applied for, and obtained, a warrant for the arrest of Jones, on the charge of perjury in connection with the evidence he tendered as above referred to. The execution of the warrant was, as pointed out, delayed till the Saturday afternoon, and finally Jones was brought before Mr. Justice Grantham and a jury at the Guildford Assizes.

At the trial the police asserted that Jones had not

been following Mr. Johnson's car on the occasion in question, although he swore that he had done so, and that he was not visible anywhere when they stopped Mr. Johnson's car. They produced two "independent" witnesses, the evidence of one of whom, however, upset the police case by corroborating the defendant's version of his actions, while the other failed to throw much light on the situation.

Mr. Justice Grantham summed up the case. After a long and rambling statement, in which he declared, at much length and with frequent repetition, that there was a great deal of feeling against motorists, that they were constantly infringing the law, that the police were quite justified in setting traps for

motorists as they did do, and that it was quite wrong for anyone to warn motorists where such traps were arranged, he concluded as follows:—

"I am astonished at the evidence given by the prisoner. It seems to me he has put himself in an extraordinary position. If his story is true, it is extraordinary that he should have acted as he did. The object of his position as a scout is to draw the attention of the police to anything going on improperly on the road affecting motor cars, and to render the police all reasonable assistance in a prosecution. He ought not to be afraid of the police. If these instructions issued to him are genuine, their object is to assist the police. Then why should he not have stopped? But he did not stop at all. When he saw a motor car in difficulty he goes away. He does not stop. Whether he was afraid of himself, and that he might get into a scrape—"

Mr. Gill (for the prisoner): If you will look at No. 4 of the instructions, my lord, you will see—

Mr. Justice Grantham: I was reading it, and showing that apparently their object is to help the police. If the prisoner sees the police talking with a motorist, why should not he stop and ask what was the matter? But he goes by and does not give his name, and actually Johnson, the man guilty of exceeding the limit, does not know he was there. What did he say before the magistrates? "I saw the car stop. The inspector and the P.C. were standing together. The car stopped before getting to the inspector. I went down the road and waited to offer my services as a witness." What was the good of going down there if he was waiting to offer his services as a witness? Why not go up to Johnson? Why not go up to the policemen? But he does not do so. (Reading) "I waited to offer my services as a witness. The car came back, and I stopped him, and he said he was not going more than 15 or 16 miles an hour. I agree with what the defendant said." Why does he not go up and say that at the time? If he was not afraid to speak to the police I think he would have done what every sensible man would have done. Therefore this statement—I do not say it is intentionally untrue, but it is apparently untrue and misleading. Because if these instructions mean anything, why, in the name of common sense did not he pull up? He saw the inspector and the man in uniform.

Photograph by Campbell Grey.

POLICE versus "A.A." SCOUTS.—The Marks trap on the Fairmile.—Where trapper Marks was "hedgehogging" behind palings upon private property. The exact spot is where a man is visible over the fence. It was from this point that Marks alleged it was possible to see a motor car coming from a bend in the road about a quarter of a mile away—a contention hopelessly refuted by means of photography. In our other picture this is demonstrated clearly.

He knows what is going on. He knows it is a question about speed, and yet he never goes up. It is the most extraordinary conduct I ever heard. Then he goes on: 'I came back after the car had been stopped.' How can he if he was behind it all the time before? That statement is inconsistent with his own story—'I will swear I was behind the car when it was timed over the measured distance.' Well, if he was, he could not have come back when the car was stopped. The whole thing is incomprehensible, and he puts himself out of court. Then as to the witness Mason. It is held that his evidence is in favour of the prisoner. His evidence is *not* in favour of the prisoner at all. In one sense it differs from that of Inspector Marks. But Mason's evidence, if you are to believe him, proves that it is quite clear the prisoner has perjured himself in his evidence, because Mason says: "I saw him before I saw the car. I saw him between Claremont Lodge and Fairmile Cottage, and he passed me." That is to say he came up from Cobham.

Mr. Gill: I am sure your lordship has got it quite wrong. He was riding *towards* Cobham.

Mr. Justice Grantham (reading): "He was then going towards Cobham, and that was before I saw the car."

Mr. Gill: Certainly. Twenty or thirty yards in front of it.

Mr. Justice Grantham: Then if he was there before the boy saw the car, the prisoner could not have been behind the car. It is as clear as possible, and it shows that Mason's evidence confirms the evidence for the prosecution, but no doubt there is a difference. Mason says: "I saw him between Claremont Lodge and Mr. Tabor's house before the car came along." Marks said he had gone by a quarter of an hour before, and gone by towards Cobham. And if he had gone by towards Cobham, Marks would not know he was coming back. It was manifest he was coming back, otherwise he would not be where he was. He had gone on, as Marks said in the first instance—he had gone on towards Cobham, like a scout, up and down the road. It is as he comes back—

Mr. Gill: I am sure your lordship is mistaken. He said over and over again he was riding a bicycle towards Cobham. That was almost at the time the car was stopped.

Mr. Justice Grantham: I took my note. "I saw the prisoner before I saw the car." It only shows he was on the Cobham side of the car. According to Mason he was on the Cobham side of the car. Whether he was going up or down is perfectly immaterial. If he was on the Cobham side Mason's evidence confirms the evidence of Inspector Marks and the other witnesses, and I think I am stating it clearly, and should be allowed to proceed without these interruptions. The question is, "Was he behind the car?" I think I am entitled to say that it is extraordinary that, being there for the purpose of being a witness, he should not go up or speak to the police, and that it was only when he met Johnson at five o'clock in the afternoon, that he spoke to him about it. It is for you (the jury) to say whether or not you believe the police when they say that this man was not there at the time the car was stopped, that he was not behind the car, that he had not been riding behind it, and that therefore his evidence was perjured, as given by him for the purpose of assisting the defendant Johnson, by saying, 'I was riding behind the car all the way along the measured distance, and therefore I have authority for saying he was not going twenty miles an hour.' If you believe his own statement that he was behind the car, is more reasonable than those of the other witnesses, then you will say he is not guilty. You must say he did the best he could for the Association. Nobody says anything against the young fellow before, but if you find that the evidence is that he said something which was untrue in a court of justice, you must return him guilty. Now consider your verdict.

The jury returned a verdict of "Not Guilty," and the prisoner was discharged.

Photograph by Campbell-Grey.

POLICE versus "A.A." SCOUTS.—A photograph of the Marks trap on the Fairmile, looking from where Marks was "hedgehogging" behind the palings. Constable Sharp claimed that he was easily able to determine when a car was exactly level with, or had passed, the gate seen in the distance, opposite which a man appears to be standing in the road. Upon this theory the main contention of the police hinged; Sharp swore that the car was about 30 yards past the gate. When confronted with the above photograph, neither Marks nor anyone else was able to say correctly where the man in the road was standing in relation to the gate. Guesses placed him 20 and 30 yards on the other side, level with the gate, and so on, but none came near the truth, viz., 30 yards this side of the gate.

⊗ ⊗ ⊗ ⊗

ONE of the good people of the type who always object to everything—a clergyman by the way—has been objecting to the amount of money spent on motor cars by the wealthy, and thinks that it would have been much better that they should spend all this wealth on improving the unhealthy homes of the people. The reverend gentleman leaves out of sight altogether the

great and increasing army of mechanics, tyre makers, oil manufacturers, and those engaged in subsidiary trades who would, if he had his way, be thrown out of work, and whose want of employment would go a long way to completely neutralising the advantages which would be obtained by the method of employing capital which he advocates.

RACES, RECORDS, AND TRIALS.

THE TOURIST TROPHY RULES—THE STEAM CAR DIFFICULTY.

If there is one thing to be deplored in connection with the Tourist Trophy Race, as a type of contest, it is that the very basis on which the rules are framed is liable to prove misleading to the general public, and to all those who fail to grasp its real significance. It is, in short, most unfortunate that the event should appear to have so close a semblance to a fuel-consumption trial, for everybody knows that the mere cost of the fuel consumed by a pleasure vehicle is quite a minor matter. For our own part, we have realised from the very first that this misapprehension was likely to arise, and it was to a great extent because we did so, that we published so comprehensive a series of articles on the subject in the present volume of *THE AUTOMOTOR JOURNAL*. The fact remains, however, that this very disadvantage—the liability of the public to regard the contest primarily as a fuel-consumption trial—is an ever present danger to the success of what is otherwise a most excellent type of contest. The fuel-consumption basis is unquestionably a most admirable method of restricting the actual power of petrol engines, and, of course, under the Tourist Trophy rules, the fuel is restricted purely for attaining this latter very essential purpose.

The other great difficulty with which we are now concerned is one that has found expression in one form or another for a very long period, though not unnaturally it has been brought into particular prominence quite recently. There has been a strong feeling on the part of those who advocate the many merits of steam cars that such cars have been debarred unfairly from taking part in the various contests of the year, and that such bodies as the A.C.G.B.I. have shown undue preference to the interests of the petrol vehicle. It does not appear to be generally recognised that, however willing the club might have been to include steam cars, it is practically an impossibility to find an equitable means of doing so, except in such purely speed contests as the Gordon-Bennett Race (where engine-power is unlimited) or in such long-duration competitions as the Reliability Trials (where separate tests can be made for various characteristics, and the competing cars can be divided up into numerous classes). Even leaving steam cars out of consideration, it has been found quite sufficiently difficult to organise any really useful event for petrol cars, and one of the greatest problems has been that of finding a satisfactory limitation or "applicable definition" of engine-power. Further than this, take the case of hill-climbing contests, in connection with which no satisfactory solution has yet been arrived at, and never will be if a formula is expected to accurately differentiate between the relative merits of a petrol car costing £150 (say a 7-h.p. Oldsmobile) and a £1,500 Mercedes!

It is just because the A.C.G.B.I. have recently attempted to modify the Tourist Trophy rules so that steam cars of an approximately equivalent character should be able to compete on nearly similar terms with petrol cars, that our correspondence columns and those of the entire motoring press have recently been inundated with letters of protest on the subject—not a few, be it noted, from dissatisfied builders of steam cars. For our own part, we cordially welcomed the straightforward statement issued by the club at the time that the

proposed rules for next year were made public, for this was the first occasion on which the real position had been defined officially, and an authoritative reason given for the apparent neglect of steam cars in club competitions. The statement then made fully demonstrated the spirit which dictated the action of the Club Committee in asking the Technical and Races Committees to devise some scheme whereby steam cars could be given their due in next year's Tourist Trophy race. And the *attempt* which was made by those committees to solve the very difficult problem was a conclusive proof of the sincerity with which the matter had been considered in all its bearings by them.

It is unquestionably a moot point whether steam cars and petrol cars should be allowed to compete against one another in the Tourist Trophy race on terms which cannot but be purely arbitrary, for the event is essentially *not* a handicap, and the very nature of the rules would—on the suggested fuel allowances—give it the characteristics of a handicap. The real point at the moment, however, is that there is an evident tendency for some of those who are interesting themselves in this subject to forget the nature of the fuel-consumption basis in the Tourist Trophy, and to regard it as a matter of cost of running rather than the limitation of engine power, which it is intended to be. The effect of giving each petrol car an allowance of one gallon for every 25 miles to be traversed is essentially equivalent to specifying a certain maximum power for each petrol engine, and of giving the Trophy to whichever car is best able to make effective use of that power in driving a car of a specified weight. Were it not for the tendency there would then be for the engines to be run at abnormally high speeds, and were it not for certain other equally good but subsidiary reasons, the cylinder dimensions might just as well have been limited instead, for that method would also restrict the power available. Thus it will be seen that nothing would stand in the way of similarly limiting the engine-power to precisely the same extent on a steam car if it were possible to institute exact comparisons between their steam engines and the latest petrol engines. But this obviously cannot be done with any degree of accuracy, and it is only in the light of practical experience at *any particular time* that even an approximately correct estimate could be made of the relative fuel-consumption of an up-to-date petrol car and of an equally up-to-date steam car. As the Technical Committee have said: "The many radical and inherent differences between internal combustion engines and external combustion engines" render it "impossible to arrive at any accurate basis by which steam cars can be placed on a precisely parallel footing with petrol cars in the Tourist Trophy race."

To make the matter worse, there is not even the same uniformity amongst the comparatively few makes of steam car that exist, with regard to the fuel they use, as there is with petrol cars. This in itself naturally constitutes a further difficulty, besides again tending to raise the false issue of "cost." No one can say what quantity of one fuel will ensure equality of engine-power as compared with another fuel on the various types of car, and it would be an entire departure from the very spirit of the Tourist Trophy rules if the cost of the fuel, or even its thermal value, were made to regulate the quantity allowed in each case.

It follows, therefore, that one has, however reluctantly, to admit that the Tourist Trophy type of contest does

not solve the great problem of providing an automobile event which is open to all types of touring car—steam as well as petrol—by enabling them to compete against one another on exactly equal terms in the same short-duration race. The most it does is to afford an excellent event for “petrol” cars (using petroleum spirit) by *themselves*, or for such steam cars as burn petrol by *themselves*, or for steam cars burning some other easily definable heavier liquid fuel by *themselves*. Any attempt to arbitrarily fix a definite relationship between type and type is bound therefore to savour of “handicap,” and is therefore open to comment. Were there as many makers of steam cars as there are of petrol cars, it might well be possible to fix one fuel-allowance for steam and another for petrol cars, in the same way that has already been proposed by the club, and let all the cars run over the same course at the same time in two distinct categories. But there are so few makes of steam cars, that this is hardly feasible, and it follows, therefore, that if steam cars are to be allowed to run at all, with any chance of winning the Trophy, the suggestion of different fuel-allowances, already made by the club, is the nearest possible approach to anything that is practicable. It is very unfortunate that there should be so much difficulty in giving a really good steam car its deserts in so important a competition as the Tourist Trophy race, but it cannot be too widely recognised that it is in no way a discredit to “steam” that this should be so.

[We now learn that, upon further and fuller consideration, the Club Committee have formally resolved not to differentiate between petrol cars and steam cars in next year's race, but that all competing vehicles will be given the same quantity of fuel. However much one may regret that steam cars are thus virtually prevented from having any chance of winning the Trophy, this latest decision will not be entirely unexpected by those who are conversant with the many *pros* and *cons* that are dealt with in the foregoing article.—ED.]

UPON the recommendation of the Races Committee of the A.C.G.B.I., as none of the entrants of the eighteen cars “placed” in the Tourist Trophy Race has claimed any award under the “British-made” resolution, the committee of the club has withdrawn the resolution for the 1905 race.

A SOMEWHAT remarkable case has just been decided by the Paris courts. On May 1st of the present year an automobile passed a cyclist on the road between Melun and Paris. The motor car raised so dense a cloud of dust that the cyclist, who was enveloped in it, could not see his way, with the result that he swerved across the road, was overtaken by another motor car, knocked down and killed. Actions were brought both against the driver of the second car, who actually injured the cyclist, and the driver of the first car, who actually raised the dust. The result has been that the driver of the second car has been compelled to pay a fine of £40 and £120 compensation, but the driver of the first car, which raised the dust, has not only been acquitted, but his claim for £8 for unjustifiable prosecution has been allowed. Let us hope that the penalties which have been incurred by the reckless motorist who drove into the cloud of dust will have a beneficial effect on the other side of the Channel.

It has also been decided that this resolution regarding special awards for British-made cars shall be embodied in the Regulations.

Hill-Climbing Formula.—The Committee of the A.C.G.B.I., being anxious to obtain some solution to the much vexed question of a workable formula for hill-climbing contests, set the Expert and Technical Committee of the Club to work to prepare a suitable one. All to no purpose, however, as after a lengthy discussion the Technical Committee have passed the following resolution:—

That in view of the fact of its being necessary, in any satisfactory hill-climbing formula, to co-relate numerous points that only permit of such co-relation on a purely arbitrary basis, it is, in the opinion of the Technical Committee, inadvisable for the Club to adopt, or sanction, any hill-climbing formula whatever, for indiscriminate application to events of this character.

The French 1906 Speed Event.—As we last week intimated, everything pointed to the decision of the A.C. de France to organise an event for big racing cars during 1906. This has now been confirmed, and considerable discussion has already commenced in France as to the circuit which is to be chosen for the occasion. In similar manner to the early part of this year, the multiplication of suitable (?) circuits is positively appalling. The most favoured of all may be taken as that of Aix-les-Bains for two reasons, primarily from the fact that the town and district is extremely wealthy, and those in power are prepared to give very substantial donations towards the organisation of the race, and, secondly, from the fact that the Gordon-Bennett Circuit being shifted this year to the Auvergne district was a great blow to the Aix municipality, who had practically regarded the choice of their roads as certain. It is to be hoped that they are not doomed to a disappointment again by the counter proposals which are on all sides being prepared by other localities where the authorities have attractive circuits to offer, including the Auvergne.

RUMOUR in New York states that an American constructor is building a 250-h.p. racing car from designs by M. Francois Richard, for Alfred G. Vanderbilt. Sartori, the Italian driver, is credited with being destined to drive this car at the Florida Race Meeting.

THE Kingsbridge magistrates are to be congratulated on their vigorous support of the local bye-laws in regard to the lighting of vehicles. In defiance of these, a carter named Henry Hart was recently drawing three wagons loaded with long fir poles along a road in the neighbourhood. The fir poles on the rearmost of the three wagons projected 30 feet behind the cart by which they were being transported, and no lamp was attached to the end of them to warn people approaching of the danger which threatened them. The result was that Dr. H. Grey, of Kingsbridge, drove his motor car into the projecting poles, his car being seriously injured by the impact. In the proceedings, Dr. Grey very justifiably termed such an arrangement “a moving death-trap,” and the Bench, rightly regarding the offence against the county bye-laws as “one of the most serious which could be committed,” fined the reckless carter 40s and 16s. 6d. costs.

CLUBS AND ASSOCIATIONS.

Founder Members' Dinner at the A.C.G.B.I.—On Wednesday of last week, the second of these interesting annual functions was held at the club, with Mr. F. R. Simms in the chair, and many were the pleasant reminiscences that were brought up amongst the "old fogeys" who were thus brought together once more. Col. Crompton proposed the toast of the evening, "Our Noble Selves," in a particularly happy vein, and his lead was well followed up by Mr. Instone (in the regretted absence of Mr. Harrington Moore), by Mr. Claude Johnson, and by the Hon. C. S. Rolls (as the youngest founder member), who responded. Referring to the comparatively small size of the gathering, more than one speaker suggested that a summer tour might prove more successful as a method of re-union for "Founders," and Mr. Edge brought forward a proposal that they should form a sub-committee of their own for securing greater cohesion, as of old. An amusing speech from Mr. Bird proved a further diversion during the evening, and Col. Holden recalled much that is of great interest in the history of the movement in proposing the toast of "the Chairman," Mr. Simms. On Mr. Johnson's suggestion, telegrams (or letters) of regret for their absence, of remembrance, and of gratitude for past services were sent to Mr. Evelyn Ellis, Mr. Paris Singer, Mr. Harrington Moore, Sir Alfred Harmsworth, and Mr. Roger Wallace.

Brighton and Hove Automobile Association.—The monthly meeting of the Association was held last week. Seventeen new members were elected. A resolution was proposed that the chiefs of police at Brighton, Hove, and Lewes, be asked to supply information regularly to the Association, notifying any cases against automobilists. A further resolution was unanimously adopted, that steps be taken by the Association to prohibit the issue of licences to unskilled drivers; and another motion protested against increased taxation of automobilists. With regard to the proposed exhibition in January at the Dome and Corn Exchange, it was resolved that a special committee be formed to collect the monies in connection therewith. Mr. J. E. Davis, M.I.M.E., was appointed consulting engineer to the Association, and it was resolved that a sub-committee be formed for the purpose of advising the Association's Committee as to the holding of examinations in Brighton for proficiency certificates of motor car driving.

Ipswich and East Suffolk A.C.—Last week, the third Annual Dinner of the club was held at the White Horse Hotel, Ipswich, Mr. F. L. Bland, the chairman of the club, presiding. An influential gathering was secured, including Mr. H. Miller, East Suffolk county surveyor; Mr. Whiting, Mr. W. P. Burton, Mr. B. W. Elkington, Mr. Rees Jeffreys, Dr. Rowe, Dr. Moseley (hon. secretary of the club), Dr. Ward, Dr. Hossack, Dr. Hoyland, Dr. Vincent, Mr. Lionel Vulliamy, Dr. Wetherall, Mr. A. E. Jillings, Mr. A. J. Snowden, Dr. Longworth, Mr. E. C. Sayer, Dr. Heath, and Canon Pigot.

Mr. W. P. Burton, in a much-applauded speech, when proposing the toast of "The Town of Ipswich and the County of Suffolk," said that those outside automobilism might say that motorists had no right to criticise the roads, because they did not pay specially for a specially good road for their enjoyment. But he contended that every Britisher paid towards the upkeep of the roads, whether in town or country. He criticised the various methods of road making in different counties, and concluded by bearing witness to the fact that the Suffolk roads were improving, and by hoping for more improvement.

Mr. Rees Jeffreys, in reply to the toast of "The Motor Union," proposed by the chairman, advocated the formation of clubs as the best way of helping to spread the light and advantages of automobilism. It would, he said, be through the existence of such clubs as he was addressing that the change would be brought about with the minimum amount of friction. In the neighbourhood of Ipswich it seemed to him there had been much less difficulty than in some other parts of the country, such as Surrey, Sussex, and some parts of Yorkshire, and he attributed that largely to the excellent influence of the local club.

Ladies' A.C.—The greater portion of Mr. R. Sedgwick Currie's fifth lesson was given in the garage behind the club. Here, upon a 25-h.p. Iris he showed the members the different parts—which they had studied separately and in detail at the previous lessons—as they are placed on a chassis. The members seemed especially pleased to be able to examine the new universal cardan shaft with which this chassis is fitted. The "Iris" had been lent to the Club by Messrs. Legros and Knowles.

The committee have asked Mrs. Manville to lecture to her fellow members at the club on her motoring experiences, more especially

those connected with the Bavarian Races. Mrs. Manville has acceded to their request and promised to reserve an afternoon for this purpose soon after her return from Egypt next February.

Manchester A.C.—Following the house dinner of the club at the Midland Hotel, Manchester, on the 4th December, 1905, a paper on the "Propagation of Flame in relation to Petrol Motors" was given by Dr. Ormandy. Mr. T. W. Grace, president, occupied the chair.

The first portion of the lecture was devoted to a discussion as to the manner of the propagation of flame through a gaseous mixture. The necessity for the conversion of the fuel into a vapour as distinguished from the finely divided spray was pointed out. The fact that the velocity of the propagation of flame through a gaseous mixture is so largely dependent upon the presence, or otherwise, of an excess of air was illustrated. The influence of compression upon the rate of propagation was also referred to. A consideration of the points touched upon in the early part of the lecture led to the conclusion that it was impossible to arrange a sparking advance by control from the governor in a way that would give the best results under all conditions, since with the engine running at any one given speed, the best position for the spark varies according to the quality of the mixture and the compression at the time. The influence of the spark and the ratio of the cooling surface to the compression space capacity was also discussed at some length, and the conclusions drawn were favourable to the cylinder without side pockets and with the valves in the head.

After the paper was over, a discussion ensued in which a number of members, including Messrs. T. W. Grace, F. Smith, J. A. Morris, and J. Lester, took part.

Society of Automobile Mechanic Drivers.—An extraordinary general meeting of this Society took place last week, when the future conduct of their affairs was discussed with the object of placing it on a sound working basis. Mr. Budd occupied the chair, and drew attention to the chief objects of the Society, which comprise an employment bureau, lectures, provision of maps, &c., and the general advancement, benefit, and protection of its members. The financial report, as presented by the treasurer, Mr. Groves, disclosed a satisfactory state of affairs. An important subject was then discussed in regard to the registration of the Society under the Friendly Societies' Act. The advantages in favour of this course were many, as the Society was intended to protect not only its members, but also owners and manufacturers, against the large number of doubtful and pretended drivers who were, by their tactics, bringing the chauffeur's profession into disrepute. The Society, it was explained, were anxious to do everything to put down frauds and expose swindles especially in connection with so-called motoring schools, and as a benefit society, amongst other things, they would be enabled to insure their members against sickness, accident, or want of employment. It was decided unanimously, therefore, that the Society should be registered under this Act.

It was further arranged that some time in January next, towards the end probably, an invitation concert should be held in order to make known the Society's objects, and thereby obtain more adherents amongst chauffeurs as well as owners and manufacturers. The annual general meeting was fixed to take place on January 15th. Mr. Groves, in reply to some queries as to the method of eliminating incompetent drivers, stated that the Society intended, through their Examining Committee, to test each candidate, and that all intending members would have to pass an examination. Those who were unable to come through this, it would be better for the Society and the whole of the industry to do without.

THE Eastern Counties Automobile Club have changed their name to the Ipswich and East Suffolk A.C. It was felt that owing to the formation of important clubs in the territorial area suggested by the name Eastern Counties A.C., it was very desirable to alter the name as it only might mislead in the future.

A LARGE number of students and friends foregathered at the Northampton Institute on Friday evening last, the occasion being the distribution of prizes and certificates awarded during the session 1904-5. At the Northampton Institute teaching in connection with automobilism is regarded as an important part of the objects of the establishment.

The Principal (Dr. Walmsley), in delivering his report, spoke of the great strides which the work had made in the session just concluded, and said they had now reached the limits of their accommodation. Among other interesting items, he mentioned that the

number of student-hours worked were now double what they were during the first session. As this practically means that the students must have worked twice as hard, it probably accounts for the long list of successes.

Sir Wm. Preece, in the course of a telling speech, dwelt upon the value of technical education to a nation, and pointed out that it is only by keeping up-to-date with our education that we may hope to maintain the supremacy of British workmanship. Probably the most striking illustration of the value of technical education to a nation was shown in the case of Japan, which in a few years had left her neighbour, China, far behind, although the latter country was intellectually the finest educated in the world.

He deplored the lack of local patriotism. Although a good many fortunes had been made in London, yet there was not a single educational institution which was adequately endowed, and he

MOTOR CYCLING.

Motor Bicycle World's Records.—On Saturday last, at the Paris Parc des Princes track, Giuppone, on a Peugeot motor bicycle weighing 52 kilogs., lowered the world's records for that type of machine for all distances up to 102 kiloms., and, in addition, for the hour. His distance for the hour was 102'368 kiloms., against Anzani's previous record of 93'78 kiloms., and his time for 100 kiloms. was 58 mins. 38½ secs., against Anzani's previous record of 64 mins. 14½ secs. The start was a standing one, and, during one circuit of the track, which measures 666 metres, Giuppone was timed for 21½ secs., equal to a speed of 112 kiloms. per hour. It is not surprising to learn under these conditions that the machine was mainly of special make in many parts, including the frame, tyres and belt. The chief intermediate times were as follows:—

Giuppone.			Anzani (Previous Record).		
Kiloms.	m.	s.	h.	m.	s.
10	...	5 34½	...	0 6 29½	
20	...	11 21½	...	0 13 1½	
30	...	17 14	...	0 19 37½	
40	...	23 8½	...	0 26 0½

THE Lewisham Automobile Club are promoting an open hill climb for tricar, to take place on January 27th.

Riley Cycle Company, Limited.—The annual report states that in the year ended September the company made a net loss of £3,996, the adverse result being due to the manufacture of motor cycles having proved disastrous owing to the considerably reduced

thought this should not be the case. While the technical side of the Institute had been so successful, he was very glad to learn they had not lost sight of the social and recreative side. The success of young Englishmen was largely due to the discipline, judgment, and self-reliance which they had learnt in the course of their recreations.

Sir William then distributed the prizes and certificates, numbering considerably over 500, and after the usual votes of thanks had been passed, the company visited the laboratories, workshops, &c., where a number of students were at work.

Both before and after the ceremony, Dr. Davan Wetton, the organist of the Institute, played some selections on the splendid organ in the large hall. On the following day, the annual conversazione was held, when the many workshops and laboratories were open to inspection, and various displays served to enliven the proceedings.

demand for the machine, and to unavoidable delay in executing the orders for tri-cars. The company have discontinued the manufacture of motor cycles, and, therefore, it has been necessary to write down the stock in hand, which partly accounts for the figure of loss.

Amongst other organisations which have been running public motor services in various parts of the country, is the Lake District Traffic Association. This Company, we learn, has had a most successful year, having paid a 12% dividend. We are pleased to reproduce above, photographs of some of their char-a-bancs which they have in regular service in Westmoreland. The vehicles are Thornycroft models; in the left photograph three of these char-a-bancs are waiting their turn for service in front of the Company's office, whilst in our right picture one of the vehicles is shown in front of the Lake Hotel, one of the points visited in connection with the Company's regular routes.

Dr. Warre, the late Headmaster of Eton, as we announced some little time ago, has been the recipient of a very delightful gift of appreciation from a number of old Etonians in the form of a British-built Rolls-Royce Car. This carriage has now been completed and is seen in our photograph above, it being convertible from an open phaeton, as shown, to a closed coupe.

Petrol and its Future.—Sir Marcus Samuel, Bart., chairman of the "Shell" Transport and Trading Company, Limited (one of the great oil-producing companies), when presiding at the company's meeting on Tuesday, made the following important statement in regard to the cost and supply of petroleum spirit:—

"The great expansion in the motor car traffic will, I am convinced, create a market for our product, and if the users of motor spirit will only be guided by experience, and refuse to listen to specious reasoning, they need have no fear whatever of any famine in petrol or undue rise in its price. We should strenuously oppose such, and will not enter into any combination having for its object the raising of the price of petrol to a prohibitive one. On the other hand, I am bound to say that the rates at which it has been sold up to the present have not been remunerative, and it would not do for promoters of automobile companies to base their calculations on prices ruling wholesale for the last few months, since these have been made unnecessarily low by competitors seeking to force a combination."

We beg to offer our congratulations to Lord Harmsworth on his elevation to the Peerage, one of the honours bestowed by the outgoing Unionist Government. The new Baron has been such a consistent and enthusiastic supporter of the automobile cause and the automobile, that all interested in the development of the movement will feel satisfaction at the honour that has been awarded to him. Among others closely associated with the movement who have been honoured by the King are, Sir H. de Stern (Baron), V. C. W. Cavendish and Lieut.-Col. Mark Lockwood (Privy Council), C. Morrison Bell and Francis Ley (Baronets), W. J. Bull and H. E. Moss (Knights), Sir E. J. Cassel (G.C.M.G.).

THERE is some evidence of a revulsion of feeling in magisterial circles in regard to police evidence, and the methods they have adopted in securing convictions against motorists. This was particularly evident in the instance that came before Mr. Plowden, on Saturday in last week, in which Mr. James Rosedale, of Bayswater, was summoned for driving a motor car at excessive speed. The speed alleged by the police was 25 miles an hour, and evidence was called for the defence to show that by the express directions given by Mr. Rosedale to the manufacturers, the machine could not have exceeded 20 miles an hour, as the gear with which it was provided would have rendered it impossible

for it to do so. Mr. E. H. Lancaster, Managing Director of the Clement Motor Company, Limited, gave evidence, and stated that the car mentioned (a 10-12-h.p. Clement), unless going down a very steep hill, could not possibly travel faster than 20 miles an hour. "As far as he could recollect," said Mr. Plowden, "this was the very first case of the kind in which the evidence of the police had been overwhelmed by the evidence for the defence (Mr. Plowden must have evidently been thinking of Metropolitan cases only, or else his memory must be a very short one), and," he continued, "that hitherto stop-watches had usually held the field, though he had often been told that these watches were very unreliable. He felt considerable sympathy with the wretched victims who had struggled in the meshes of this net, for he knew that they smarted under what they thought was a grievance.

At last, however, the long succession of easy victories scored by the police had been checked, for he had decided to dismiss the summons."

EVEN from Chertsey—a Bench which in the past has earned an unenviable reputation in regard to motor car cases—a similar somewhat notable dismissal of a case is recorded. It is specially noticeable because the summons was taken out by Inspector Jarrett, who is now at Egham, whither he was some time ago promoted, as our readers will remember, from the Ripley Road. The intended victim in this case was Mr. Thomas Wilson, chauffeur to Mr. John Kennedy, of Aldford Street, Park Lane, who was haled before the Bench on the usual charge of "unlawfully and recklessly or negligently, or at a speed or in a manner dangerous to the public, having regard to all the circumstances of the case." The Bench ordered the summons to be amended to one for reckless driving only (whether legally we are not quite sure). The driver saw no constable anywhere near the place at which the offence was alleged to be committed, and Mr. Nigel Kennedy, son of the owner, bore out the evidence to this extent, that he once heard a shout, and on looking back saw a constable some distance in the rear, but he did not associate the constable and the shout with one another. The result was that the case was dismissed.

The Dunlop Company's new security bolt (on the left) which they have constructed in such a way that it is no longer possible for it to cockle up under adverse treatment into such an invertebrate object as that which is illustrated next to it in the above photograph. The canvas tabs are now stiffened with a lining of rubber which prevents them from ever becoming limp, at the same time that it leaves them as flexible, for all practical purposes, as they were before.

The Basingstoke Canal.—Mr. William Carter, of Parkstone, who recently purchased the Woking, Aldershot, and Basingstoke Canal, has, it is now announced, throughout been acting in conjunction with the Joint Stock Trust and Finance Corporation, Limited, who are now the absolute owners of this waterway.

CONGRATULATIONS to Mr. J. C. Percy upon his being appointed, by their Excellencies the Lords Justices of Ireland, a Justice of the Peace for the Borough of Dublin. Mr. Percy's very wide circle of friends on this side of the Irish Channel will no doubt join us in our congratulations upon this appointment to so popular a personality in the automobile world.

NEAR the Sundial, Botanical Gardens, Sydney, New South Wales, is the delightful spot from which we have just received a hearty Christmas greeting from Arthur Ellerthorpe, a personality in the motor world who has been for the last month or two sadly missed at the many pleasant functions which have recently been held. Mr. Ellerthorpe's many friends will wish him a speedy return to London, restored entirely to health.

THE Automobile Club of Austria is arranging a great automobile exhibition to be held in the buildings of the Gartenbau-Gesellschaft, Park Ring, Vienna, from the 15th to the 28th of March next.

BRITISH EXPORTS AND IMPORTS OF MOTOR CARS, &c., FOR 1905.

NOTE.—For 1904 comparative figures see full table for the year in our issue for January 21st, page 91.

NEW ISSUES.

Argyll Motors (Limited).—The capital of this company is £500,000 in 350,000 ordinary shares of £1 each and 30,000 preference shares of £5 each, of which have been issued 250,000 ordinary shares of £1 and 20,000 preference shares of £5. The present issue consists of £100,000 4½ per cent. first mortgage debenture stock at par, and has been made owing to a further considerable extension of the company's works having become a matter of immediate and pressing necessity.

NEW COMPANIES REGISTERED.

Anciens Etablissements Panhard-Levassor (English Patents), (Limited).—Capital, £1,000 in £1 shares. Object, to acquire patents, &c., in connection with motor cars, &c.

Automobile Industries (Limited), Winchester House, Victoria Square, Birmingham.—Capital, £15,000 in £1 shares. Object, to adopt an agreement with J. Roche.

City and Suburban Motor Cab Company (Limited), 32, Old Jewry, E.C.—Capital, £100,000 in £1 shares. Object, to adopt an agreement with the Transit Syndicate, Limited, and also to enter into an agreement with MM. Georges Richard et Cie for the supply of "Unic" (petrol) cabs, to cost £284 each, fully equipped. First directors, Sir Henry Seton-Karr, C.M.G., M.P. (vice-chairman of the London Motor Omnibus Company, Limited), Colonel T. H. Anstey, G. C. Isaacs, J. O. Lawson-Johnston, J. C. Macdonald, M.P. (director of the Fire-Resisting Corporation, Limited), and C. Wyndham-Quin (director of the Motor Exchange of Great Britain, Limited).

Co-Operative Factors (Limited), 7, Sweeting Street, Liverpool.—Capital, £2,000 in £1 shares. Object, to carry on the business of manufacturers and factors of cycles, motors, aerial machines, &c.

Fife Submarine and Engineering Company (Limited), 100, Winchester House, Old Broad Street, E.C.—Capital £10,000 in £1 shares. Object, to acquire the benefit of certain existing inventions in relation to the storing of liquid and compressed air or gases, for motive-power engines, and re-condensation of the exhaust, and other inventions by C. W. Fife.

J. E. Hutton (Limited).—Capital, £40,000 in £1 shares (20,000 six per cent. preference). Object, to acquire the undertaking of J. E. Hutton, in connection with motors, motor cars. First directors, J. E. Hutton, J. A. Sirling, and L. C. Rawlence.

Kirsh and Co. (Limited), 22, Paper Street, E.C.—Capital, £3,000 in £1 shares (1,000 ten per cent. cumulative preference). Object, to take over the business of a manufacturer of motor and general clothing, carried on by Solomon Kirsh, at 22, Paper Street, E.C. First directors, R. Starke and S. Kirsh (managing directors for thirteen years).

Mercury Motor 'Bus Company (Limited), 69, Victoria Street, S.W.—Capital, £20,000 in 2,000 preference shares of £5 each and 10,000 ordinary shares of £1 each.

Motor Users Proprietary Company (Limited), 18, Fleet Street, E.C.—Registered with 1,000 members, each liable for £1 in the event of winding up. Object, to encourage and develop in Great Britain the automotor vehicle and allied industries, and to protect the interest of members.

National Radiator Company (Limited).—Capital, £50,000 in £10 shares.

F. Ostler and Co., Limited.—Capital, £2,000 in £1 shares. Object, to carry on the business of agents for motor cars.

COMMERCIAL POINTS.

A COMPANY has recently been formed, at Genoa, under the title of Fabbrica Ligure di Automobili, to build motor vehicles and motor boats under the patents and designs of John I. Thornycroft and Company, Limited, at special works being constructed at Spezia. This is a suitable place to carry on both the boat work and the motor work generally, there being a good supply of highly-trained mechanics as a consequence of the Italian Arsenal being situated there. The Chairman of the Company is Count Gamba, and the other members are influential people in Northern Italy.

MR. ARTHUR BROWN, of Luton, who had such a serious accident near Brighton in July last, is now, we are glad to learn, sufficiently well to again take an interest in motoring, and has ordered a 60-h.p. 6-cylinder Napier.

THE Earl of Crewe has given an order to Messrs. Charles Jarrott and Letts, Limited, for the building of a Crossley motor carriage. It will be fitted with a Limousine carriage body, which portion of the work has been placed in the hands of Messrs. Hooper and Company.

IN order to remove misconception regarding the Argyll agency in Plymouth and district, we are asked by Argyll Motors, Limited, to

state that their agents are Messrs. H. Andrew and Co., Athenæum Place, Plymouth.

THE annual fancy dress ball of the Coventry employees of Messrs. Humber, Limited, was held at the Coventry Assembly Rooms on Friday evening of last week. There were 260 dancers, and about 800 spectators. The ball was favoured by the presence of Mr. W. Phillips, the Coventry manager of Humber, Limited, and a number of the leading officials of the company, in addition to many visitors well known in the cycle trade. The whole affair was a most successful function, and served to demonstrate the unanimity and goodwill which exists in the Humber firm.

THE sole agency for the London district of the Hele-Shaw Patent Clutch Company has, we learn, been placed in the hands of Messrs. Gauthier and Company, of 60, Great Marlborough Street, W.

A CABLEGRAM to hand announces, we are informed, conspicuous victories for Dunlop motor tyres in the important annual motor car event between Melbourne and Sydney. The course is a difficult and trying one, involving a considerable strain upon cars. Of the sixteen cars which reached Sydney thirteen were shod with Dunlop tyres. A further run of 700 miles resulted in five cars tying, four of these being fitted with Dunlop tyres.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

2493. 7th February, 1905. Improvements in Self-propelled Vehicles. Albert G. Davis, Schenectady, State of New York, U.S.A. Date under International Convention, 8th February, 1904. In this invention, a prime mover, such as a gasoline engine with an electric generator driven thereby, is employed, thus obtaining the convenience and flexibility of electric drive and eliminating the necessity of using speed-changing gears. One feature of the invention consists in the arrangement of the motor driven by the generator and its circuits, whereby operation at a number of speeds and gradual variation of speed and torque may be readily and efficiently obtained with a single motor. There are four figures. Fig. 1 shows a plan view of an automobile with the car body removed. A is the main frame of the automobile, upon which is supported the car body and to which is secured in the usual manner the bearings for the wheels, W. C is an auxiliary frame upon which are mounted the motive parts of the machine, and which is supported from the main frame, A, by a three-point suspension. The frame, C, may be secured at one end to the frame, A, by bolts and at the other end may be supported from frame, A, by a hook or nose, or by any other form of single point suspension. The three point suspen-

sion, F, is carried by the engine shaft. With this arrangement the motor may be driven by the generator for the lower speeds, and when full speed is reached the motor shaft may be clutched to the engine shaft and the motor circuit opened, thus saving all losses in the motor. The rear end of the motor shaft drives the differential gears, D, which are connected through sprocket chains to the wheels in the usual manner. The arrangement of engine, generator and motor in alignment and supported from a single frame forms a compact unit of the active parts, enables the engine shaft to be clutched directly to the differential gears without transmission losses and ensures the maintenance at all times of the proper relations between the motive parts. H is a band brake, which may be of any well-known type, and which is operated through a bell-crank and through the rod, A¹, by the brake pedal. — November 22nd, 1905.

1047. 19th January, 1905. Improved Apparatus for Deadening Mechanical Shocks Experienced by Moving Vehicles. Pierre Robin, 71, Rue de Pro-

press upon the leather. Within the piston, *i*, is a second piston, *j*; the joint between this piston, *i*, and the interior cylindrical wall of the piston, *j*, is made by means of a leather cup-ring, *c*¹, secured in the same way as the cup-ring, *c*², secured in the piston, *i*, is limited in both directions by flanges, *j*¹, *j*², abutting against the end plate or cover, *j*³, secured to the piston, *j*. The stroke of the piston, *j*, is limited in one direction by the cover, *j*³, which abuts against the barrel of the cylinder, *a*, and in the other direction by the head of a rod, *a*¹, secured to one of the end plates of the cylinder, *a*, and engaging with the end plate, *j*³, formed with or attached to the piston, *j*. This end plate, *j*³, is provided with orifices, *j*⁴, for the admission of compressed air supplied through the pipe, *a*², from the air reservoir. The end plate of the cylinder, *a*, and one of the bases of the ball and socket joints, 18, 19, serve for mounting the improved apparatus on the vehicle frame. The improved apparatus can be interposed between the wheels and the frame sockets, 20, carried by lugs, 21, made in one with the frame, 22, and the balls, 19, are articulated in the sockets, 20, and the connecting-rods, 24, which are secured at one end to axles, *r*, and are articulated at the other end to the frame. The rods, 24, connect the axles, *r*, with the vehicle frame while allowing them as much play as the elasticity of the apparatus permits. Further, by placing the joints of the connecting-rods of the rear wheels on the axle or shaft of the chain pinions, 25, the distance between the pinions, 25, and the pinions keyed upon the rear axle, and also the tension of the chain will remain constant. The tension can be adjusted by means of screws, 26. — November 22nd, 1905.

sion of auxiliary frame, C, from frame, A, ensures that any strain or bending of frame, A, due to rough or uneven roads will not be transmitted to the auxiliary frame, C, and to the motive parts carried thereby. Supported from frame, C, is the prime mover, E, a gasoline engine. Mounted on the shaft of the prime mover, E, is the revolving part or armature of the generator, G, the stationary part of field of which is secured to frame, C. The armature is placed outside of the field in order that the proportionate weight and the radius of gyration may be increased so that it may act as a fly-wheel for the engine, E. Also secured to frame, C, is the motor, M, which is placed with the shaft in line with the engine shaft, and which carries at one end of its shaft one member of the clutch, F. The other member of the clutch,

ence, Paris, France. This invention relates to an improved apparatus for deadening mechanical shocks, such as those to which the wheels of moving vehicles are subjected, by substituting pneumatic springs for the metal springs usually employed. There are seven figures. Fig. 1, is a central section of the pneumatic spring, and Fig. 2, is an elevation of the frame and wheel. The apparatus comprises a cylinder, *a*, in which moves a piston, *j*. The joint between this piston and the body of the cylinder is made by means of a leather cup-ring, *c*¹, secured upon the piston by a washer, *d*¹, screwed on the piston, *j*. To ensure the contact of the leather cup-ring with the cylinder, *a*, a crown, *e*¹, is interposed between the washer, *d*¹, and the leather. This crown is provided with teeth which act as a spring and

PASSING EVENTS.

The Election Question.

THE letter of Lord Harmsworth to the Press, to which we referred last week, and in which he recommended to automobilists that they should, as a matter of principle, refrain from supplying any motor cars at the impending General Election for the support of any candidate who does not pledge himself to progressive legislation on the motor car question, is bearing fruit in the form of a very voluminous and very lively correspondence. It is satisfactory to find that Lord Harmsworth's proposal is securing as we hoped it would do, the support and adherence of the great majority of motorists. The whole question was considered in detail this week, at a meeting of the provincial delegates of the Automobile Club and a committee of the Motor Union, when a regular plan of campaign, with a view to the approaching Election, was discussed and arranged for. The Motor Union at present suggests putting certain definite questions to intending candidates, with a view of ascertaining their position on the automobile question. The questions are as follows:—

1. When the Motor Car Act of 1903 comes before Parliament for renewal, will you vote for:—
 - (a) The abolition of all artificial speed limits, as such limits are calculated to relieve drivers of their responsibility to drive at all times and under all conditions with caution and consideration?
 - (b) An amendment providing that the endorsement of licences shall be confined to serious offences, and be within the discretion of the magistrates?
2. Will you support a measure requiring the universal lighting of all vehicles after dark, so that they show a white light in the direction in which they are travelling, and a red light in the contrary direction.
3. Will you support a Bill giving effect to the principal recommendations of the Departmental Committee on Highways, and establishing a central authority to advise and assist the local road authorities?

Possibly Too Elaborate.

OF course we approve of all these things. We would like to see every Member of the House of Commons pledged up to the eyes to support them. But we think that in asking candidates for Parliamentary honours to pledge themselves to the whole three, the Motor Union is asking just a little too much of human nature. There is no advantage in this world in asking more than a certain excess over and above what you are likely to get, and there is many a prospective Member of Parliament who might be quite willing to vote for the abolition of the speed limit and to support the general progress of the automobile movement without necessarily seeing his way to pledge himself to the sweeping reform of our highways administration. If we can get Members to support that proposal so much the better. If we can induce them to favour a universal Lighting Bill, so much the better also, and if we can enlist their sympathies in favour of the repeal of the absurd provisions about endorsing licences, that also will be an advantage. But the main thing, after all, is the abolition of the arbitrary speed-limit. If candidates pronounce themselves in favour of that, and give a general assurance that they will promote the interests of the movement, that, we think, ought to be sufficient, and if we have evidence of the pledge having been given, it should be all that we need from a Parliamentary point of view also.

The Paris Salon Second in the Field.

THE wisdom of the Society of Motor Manufacturers and Traders in holding the great English Exhibition in November of this year, was plain enough to all who visited it, even before the Paris Salon opened its doors. But if there were any lingering doubters on the subject, their doubts would certainly have been removed by a visit to the great French Exhibition. It was not that the French Salon was less gorgeous or less representative of the year's French industry than before. As our readers will have gathered from the impressions we published of it last week, it was not only equal but superior in all these respects to its predecessors. The progress marked was as great, the exhibits themselves as interesting, and the decorations and illuminations, always tasteful, were even more elaborate, more artistic, and more effective than ever. But it was not the show of the year, and its importance for one great army of purchasers, the purchasers whom the French themselves recognise as their most important customers, was accordingly seriously handicapped. There has been nothing like the same attendance of British visitors as on previous occasions. Even those who are pre-eminently enthusiastic about Continental cars had had their opportunity at Olympia of seeing and examining the best French models and doing business, where they desired to do so, with the English agents of all the great foreign firms, who were there represented, while the benefit to the English manufacturer of being first in the field on the 1906 market was most pronounced. If any further evidence were needed, it is provided by the conversion to this view of Mr. Charles Jarrott, whose letter on the subject we publish in our correspondence columns. He, it will be recollected, was not in accord with holding the English show in November. He now reads his recantation. He has completely changed his view, and no better evidence of the wisdom of holding the Olympia Exhibition at the time it was held need be asked for.

Motor Volunteers in 1905.

THE official Report of the activities of the Automobile Volunteer Corps during the past year, will be pleasant reading for everyone who desires to see the application of the automobile to military purposes extending, as it should do, and becoming a real source of strength to the national defence. The membership of the corps has gone up till it now stands at 159 active members of all ranks, and during the past year the members of the corps have performed duties on 124 occasions. They gave a specially good account of themselves at the great review held in honour of the King of Spain at Aldershot, where a strong detachment was specially ordered by His Majesty King Edward to be present. The corps has carried out in the most efficient manner all the duties which military automobilists can be required to discharge, including not only reviews, but staff tours, signalling operations over long distances, and the maintenance of communication, supervision and inspection during manoeuvres. The record is a highly creditable one, and the officers of the corps are to be thoroughly congratulated on it. There should be no doubt now that the corps will advance from year to year both in numbers and in ability to be of assistance in the defence of the country if any occasion for their services, in grim earnest, should ever arise.

The Road Makers.

If we ever ultimately succeed in attaining in this country an adequate system of carefully managed, properly surfaced, adequately repaired, and centrally controlled roads, the moving spirits of the Roads Improvement Association will certainly deserve canonisation as the patron saints of the new and improved highways. Whenever an opportunity has presented itself of advocating any proposals by which the road administration of the country could be benefited, the association, guided by Mr. Rees Jeffreys, the energetic hon. secretary, has always been prominent with practical and useful suggestions, and now puts forward a particularly sensible and appropriate one in a letter (signed by Earl Cadogan, the Hon. A. Stanley, the president and vice-president of the association respectively, and Mr. Rees Jeffreys), which we publish this week in our correspondence columns, pointing out that in the roads of the United Kingdom we have a sphere pre-eminently adapted for useful work by the unemployed. It is a class of work in which unemployed labour would result in a benefit to the community, instead of partaking of the perfectly useless character it has usually been in the past, and it would not have the objection, to any serious extent, of competing with the employment of those already occupied.

There is a large and growing fund at present available for the relief of the unemployed. No one suggests that it should be handed to them in mere doles for doing nothing. That would merely mean pauperisation on a colossal scale, and the most deserving of the unemployed would be the first to resent anything of the sort. In general, the planning of relief works is not easy, but here is a style of work in which unskilled labour can be really made effective, and in which, indeed, at present nothing but unskilled labour is employed. Every new road made, every hill, the gradients of which are rendered more negotiable, and every badly made-up road which is given a good surface, is a gain to the community. Here, obviously, is the proper field for relief works, and the Roads Association are doing a public service in drawing attention to it.

The Sinews of War.

THE Motor Union draw attention to the fact that their war chest is not nearly so well supplied with funds as the exigencies of the movement at the present moment render desirable. Up to date the sum of £1,150 has been contributed towards the Legal and Legislative Defence Fund of the Union. Of this amount £750 has been already expended in such useful objects as giving special grants to members to assist them in the defence of cases of special importance to automobilists generally; in collecting evidence to put before the Royal Commission on the Motor Car Acts; in prosecuting offenders on the highways, and in opposing unjustifiable applications by local bodies for the imposition of the 10-mile speed limit. The Motor Union Defence Fund, therefore, at the present moment, only possesses a balance of some £400. It is true, of course, that an unusual demand was made on the Union's exchequer by the Legislation Fund of the Joint Committee, to which the Union contributed £500 of the £750 referred to above to enable a satisfactory case from the automobile point of view to be placed before the Royal Commission on the Motor Car Acts. In this respect the Union has done good service. But it is unnecessary to point out that this balance of £400 is quite inadequate for the

requirements and duties which the Union is called upon to discharge. A single important case which the Union might happen to feel it advisable to support might sweep it all away. In fact, automobilists generally cannot feel satisfied that they have in the Motor Union a force behind them whose backing is likely to be really useful unless the reserve fund the Union possesses for such purposes as resisting unjustifiable prosecutions runs into thousands at least. All members of the Union, therefore, and all automobilists, whether members of the Union or not, will be consulting their own interests and the interests of the movement by bearing this condition of affairs in mind, and as the season is now approaching when everybody takes a special pleasure in putting his hand into his pocket, it is to be hoped that the funds of the Union will be largely augmented, and that the first months of the new year may see a satisfactory reserve (which is but too likely to be needed during the ensuing summer) at the Union's disposal.

The Perjury Hunt.—The astonishing and ludicrous features of the "Guildford Perjury Hunt," with which we dealt at length editorially and otherwise in our last number, excited our indignation to such an extent that we omitted to do full justice to those who were largely instrumental in the satisfactory outcome of the proceedings. Mr. Gill we indeed mentioned, but we should have further noted that he was assisted in the skilful defence by Earl Russell and Mr. E. Cockle. Mr. Guy Lushington, who appeared for the Treasury, conducted the prosecution with strict fairness—a fairness which was in marked contrast to the extraordinary prejudice displayed by the judge, who, as our readers will have gathered, appeared to act not only as judge, but as "prosecution counsel" as well.

Driving and Proficiency Certificates.—The last of a series of provincial examinations by the A.C.G.B.I. for the present year was held at Lincoln, Northampton, Bury St. Edmunds and Norwich at the beginning of the month.

As a result of these examinations ten candidates were granted driving certificates, and seven mechanical proficiency certificates. The candidates come from very various ranks in life, and include such different callings as grooms, draymen, ships' stokers, clerks, and labourers. It is obvious that the unemployed (with intelligence) are finding out that motor car driving provides them with an opportunity.

The club's scheme of holding the examinations has been of great educational value to paid drivers. It was thought by some that the questions asked in the written paper forming part of the examination for the driving certificate were too difficult for the candidates. It has, however, been found that the necessary knowledge was easily acquired by little more than a superficial reading of the Motor Car Act, 1903, and the L.G.B. Regulations, 1904, in regard thereto. The progress in this particular part of the examination is shown by the following facts:—

In the London examinations it was found that in the first two, 40 per cent. of the candidates succeeded in obtaining the qualifying percentage, but the percentage in those held after increased to nearly 70 per cent., while in the provincial examinations the percentage has been even better, viz. 80 per cent.

THE BIG FRENCH RACE FOR 1906—WHICH COURSE ?

F

AMONGST the numerous circuits proposed over which to hold this big race about July next year, that starting from Fontainebleau is receiving an enormous amount of support from those organising the race. Its close proximity to Paris (about 50 kilometres) is naturally one of its most important attractions, and provided the report of the Commission, which is now studying the circuit, is in any way favourable, every effort will be made to endeavour to induce the French Government to sanction the holding of the race in this district. Seen on the map, the route, which measures 85 kiloms., hardly looks a promising

one, comprising as it does three circuits converging at Fontainebleau, two of which are of comparatively fair size, and one very small triangle. Starting from Fontainebleau, the present circuit is to Melun, Pringy, Chailly, Fontainebleau (end of first circuit), Arbonne, Acheres, Ury, Fontainebleau (end of second circuit), la Croix-Saint-Herem, la Croix-Montmorin, Fontainebleau (end of third circuit). We are able this week to give some photographs of some features of this proposed three-circuit course, which, if selected, would have to be covered many times—without any neutralised sections of any sort.

FRENCH 1906 RACE.—The Fontainebleau Circuit. An acute turning at Pringy.

SPEED LIMITS IN 1916.

"ACCORDING TO COPPER."

At Downshire County Bench, before Mr. Alderman Sideslip, the Reverend Mr. Chadband, and the Lord Nozoo, Captain Blank was summoned for that he did feloniously exceed the legal limit of speed laid down in the Act of Parliament, Edv. VII., Sec. 302, Fugere 1, Opus 8, when hunting with the Downshire foxhounds.

Inspector Hedgehog deposed that at noon on the 18th inst. he timed defendant over a measured distance on Muggs Farm between the mud-heap and the second ditch. Defendant was riding a powerful bay, with a white stocking and a bad temper. He timed defendant on a signal from Sergeant Slop, who was disguised as a gentleman and hiding behind the mud-heap. The horse covered the distance in forty-nine seconds, equivalent to twelve miles and three yards an hour, while the maximum speed allowed is twelve miles.

Cross-examined by Counsel for Defendant: There was no one else on the horse; there was traffic on the road. Pressed on this point witness admitted that all he meant was that a steam-roller was at work half a mile away.

Counsel for Defendant: Is it not a fact that while all your police were timing the hunt, information reached you to the effect that a woman was being beaten into unconsciousness in Lobham Village, and that you refused to leave your work?

Inspector Hedgehog appealed to the Bench, who ruled the question out of order.

Counsel for Defendant: But is it true?—Inspector Hedgehog: Yes.

Captain Blank went into the witness-box and swore that it was impossible for the horse to have covered the distance in the time, because he was not hunting at all on that day owing to a severe cold.

Fifteen witnesses corroborated defendant's testimony.

The chairman said that the evidence implied that the inspector had made a mistake, which was impossible.

Fined five pounds and costs or fourteen days.

Mary Jane McCarthy, nursemaid, was summoned for exceeding the legal limit while wheeling a bassinet in Durbiton High Street, on the 19th inst.

Inspector Hedgehog said this was a most serious case. On Saturday morning, the 19th, he set a police trap between the "Blue Bore" and the chemist's shop. He timed defendant with his four-and-elevenpenny stop-watch, and found that she covered the distance by at least four-fifths of a second in advance of the time allowed by law. P.C. Short then came out of the "Blue Bore" and arrested her.

Defendant: Did not you call out "Whoa, Beauty?"—P.C. Short: Yes.

Defendant: And I smacked your face.—P.C. Short: You did. (*Sensation.*)

Miss McCarthy, who defended herself (uncommonly well), stated that it was impossible for her to have walked so fast, because there was a hat-shop in the measured distance. She also spoke to a soldier.

The Chairman warned witness to be careful.

Defendant's mistress gave evidence, and swore that Mary Jane had never been known to do anything quickly in her life.

The Bench said the law must be obeyed.—Fined 40s. and costs or a month's notice.

Simpson Clarke, bachelor, aged four years, was summoned for riding his bicycle-horse down his father's garden path at a furious rate, further for not having the identification number properly displayed, and refusing to show his licence when called upon to do so.

Defendant was represented by his mother.

Inspector Hedgehog deposed that on Saturday afternoon, the 19th inst., he took up a position in the next garden and timed defendant over a measured distance between the dog-kennel and the third croquet-hoop. (*The Ordnance Survey Map—specially enlarged to cabinet size—was produced for the guidance of the Bench.*) It was impossible to see the number on the horse. When arrested and ordered to show his licence, defendant cried, whereupon defendant's bulldog ran out, bit witness in the leg, and harried him out of the gate. (*Applause in Court, which was immediately cleared.*)

By the Chairman: Was there any traffic on the path?—Yes, a worm, which only escaped being run over by the skin of his teeth.

The Chairman: Is the worm present in Court?

Mrs. Simpson Clarke (looking hard at the Inspector): I can see *one* worm.

Cross-examined by Mrs. S. C.: Witness admitted that the identification number was fixed on the horse, but defendant's pinafore covered it, and this constituted an offence under the Act.

Mrs. S. C.: Why were you not out trapping motorists?—Inspector Hedgehog: The A.A. patrols were on duty.

Mrs. S. C.: Is it not a fact that you have what is called "got up" this case against my baby?—The Inspector refused to answer.

Mrs. S. C.: Didn't you come trying to court our cook while all the time you have a wife and five children?

Inspector Hedgehog appealed to the Bench, and the Chairman woke up.

The Bench decided that witness must reply.

Inspector Hedgehog then admitted that this was so, but mentioned in extenuation that two of his children were married.

Defendant's mother then addressed the Court.

She said: "I have brought my purse with me because I know that justice is an unknown quantity at this Court, but I am going straight to call upon your wives, and tell them the truth about this matter." (*Sensation.*)

The Bench consulted in private (and in trepidation), and, on returning, the Chairman said:—

"The Court is of opinion that although and notwithstanding the fact that Defendant is guilty of a grave breach of the Law in having allowed and permitted the number of his bicycle-horse to be covered by his "pinny," and that whereas nevertheless an endorsement on Defendant's licence might, could, and most probably would, prejudice his career at the kindergarten, it is consequently and indisputably a case in which the glorious mercy of the English Law may be invoked, the Court will, therefore, take advantage of the Summary Jurisdiction Act of A.D. 407, and the summonses are dismissed.

S. C.

HIGH-TENSION MAGNETO IGNITION.—PART XX.

THE LACOSTE SYSTEM—(continued).

The Condenser.

ON account of the fact that the distributor-spindle, D^6 , passes from end to end between the magnet limbs, it has been necessary to make the condenser, F , of somewhat unusual shape in order to accommodate it above the

FIG. 4.—The Lacoste High-Tension Magneto. Sectional drawing showing the construction of the Armature, which has flanged brass Side Plates, A^2 , riveted to the laminated core. The End Plates, B^2 , are attached to the side plates by screws in the usual way.

armature, where it has now become general practice to place it. Constructed in an annular form, the Lacoste condenser is threaded over a sleeve surrounding the spindle, D^6 , and it is thus supported without any other attachment. Unlike most condensers placed in this position, this has no metal case, being merely covered on the outside by insulating tape. It must be re-

The High-Tension Gear.

All the high-tension connections are made at the opposite end of the armature to those of the low-tension circuit, and they are thus quite isolated from it. The collector contact, D^2 , the feeder contact, D^2 , and distributor contacts, D^3 , are all embedded in solid insulating material which is cast into the aluminium case, D^{10} . The spring contact, D^2 , which presses against the live end of the secondary winding, D^1 , conveys the current to the feeder contact, D^3 , through a metal bar also embedded in the insulator, and from the contact, D^3 , it is distributed by the revolving brush, D^4 , to each of the contacts, D^3 , in turn. These are connected to their respective terminals in the plug-board, D^{11} , from which wires are led to the engine.

The revolving member of the distributor is mounted on the spindle, D^6 , which is carried on ball-bearings, and is driven by a train of gear wheels, D^7 , D^8 , and D^{16} , from the other end of the armature spindle. In this, the Lacoste magneto follows usual practice, but it will be noticed that a compound idle wheel, D^{16} , has been introduced between the wheels, D^7 , and D^8 , in order to reduce their diameters. This idle wheel is also mounted on ball-bearings.

Timing the Ignition.

In general principles the timing gear on the Lacoste magneto resembles the mechanism which we have already described as being fitted to the Eisemann magneto. Its object is to rock the armature relatively to the shaft which drives it, and by so doing to alter the

FIG. 5.—The Lacoste High-Tension Magneto. Views of the Bearing Plate, M , which carries the gear wheels for driving the Distributor Shaft, and also of the Armature in place between the magnets. This latter view clearly shows the arrangement of the two Brushes (one carbon and one copper), C^4 , used for collecting the Low-Tension current from the Armature.

membered, however, that it is still well protected, because of the enclosed nature of the machine as a whole. The live side is connected direct to the brushes, C^4 , and the other side is earthed in the usual way, so that the condenser is "shunted" across the contact-breaker.

instant at which it reaches the "maximum" position relatively to the engine crank-shaft. In this machine, however, it is the coupling-sleeve itself which is moved to and fro instead of a sliding key as is the case in the Eisemann system. Spiral grooves, K^3 , are cut in both the armature spindle, B , and also in the engine-driven

spindle, B^1 , and internal keys on the sleeve, B^2 , couple these two members together, and at the same time allow the one to drive the other. On the outside surface of the sleeve, B^2 , are several peripheral teeth (not a thread), which engage with a toothed quadrant, K^1 . This quadrant is operated through the timing-lever, K , by moving which the sleeve, B^2 , can be slid backwards or forwards, so that the wedge-like action of its internal pins, engaging in the spiral slots, causes the armature and its driving-shaft, B^1 , to assume different relative positions. In this way the ignition can be advanced or retarded as required.

Owing to the opposite directions of the spiral slots in

FIG. 7.—The Lacoste High-Tension Magneto. Views of the Bearing Plate, M^1 , which carries the High-Tension gear, and of the Casing, D^{10} , which carries the High-Tension contacts embedded in solid insulating material. The Case, D^{10} , is of course attached, by screws, to the Plate, M^1 .

the two members, the sleeve, B^2 , is in equilibrium so far as any longitudinal forces are concerned, and there is, therefore, no strain on the connections and no difficulty in moving the sleeve in either direction while the machine is in use.

This timing-gear, which is entirely enclosed in an aluminium case, is well illustrated by Fig. 8

FIG. 8.—The Lacoste High-Tension Magneto. Sectional drawing, showing the "Timing" gear, by which the Armature is rocked over relatively to the shaft, B^1 , which is coupled to the engine.

FIG. 6.—The Lacoste High-Tension Magneto. View of the Bearing Plate, M , showing the Low-Tension gear, which is mounted about the half-speed distributor shaft. The Cam, B^4 , has, therefore, four projections instead of two.

where it will be noticed that the armature spindle passes through the spindle, B^1 , which is thus self-aligning. The same illustration shows the ball-bearing, M^2 , by which both these shafts are supported.

(To be concluded.)

American Tramways.—We have to thank the London County Council for a very interesting report by their Chief Officer on Tramways, Mr. A. L. C. Fell, on the results of his visit to America to examine the methods of tramway propulsion and organisation in use in the United States. The report is, of course, more of interest to the

electrician than the automobile engineer, but the fact should be noted that Mr. Fell reports that on several lines, in outlying districts of course, where, needless to say, there is much less traffic on the roads than in the United Kingdom, speeds of 50 miles an hour on tramways along the sides of the roads are not at all infrequent.

PARIS SALON 1905.

(Continued.)

Six-cylinder Cars and Racing Cars.

ON one other point, too, this year's Salon is disappointing, there are practically no 6-cylinder cars—the Napier, the Louet and Badin, and the Cottureau being the only examples which have come before our notice—and of these the Cottureau engine is on a racing car and the Louet and Badin on a vehicle which looks somewhat unsuitable for general use—although the only model exhibited was conspicuous for its signs of travel.

There are, however, quite a number of racing cars exhibited in places of honour on their respective stands, among them being Théry's Richard-Brasier, which won the last Gordon-Bennett, the 100-h.p. Itala, which secured the Florio Cup, and the Mors, which carried off the

sound touring vehicles. Among such cars may be included the well-known Chenard and Walcker chassis, which has the rear wheels driven by internal spur gearing. Similar in principle, although somewhat different in detail of arrangement, is the C.I.E.M. car, which was introduced last year. On this latter model, it will be remembered, a special feature was made of the great accessibility of the various parts of the engine. Another car, employing a stationary axle in conjunction with another live shaft for driving the wheels, is the Aries, but in this the wheels are driven direct, and the arrangement is chiefly adopted in order to facilitate the splaying of the rear wheels—a feature on this car as well as on the De Salvert already referred to. Then, of course,

THE PARIS SALON.—Main entrance to the Grand Palais in Avenue Nicholas II. At night the view from the steps of the Petit Palais—from which this photograph was taken—is hardly to be surpassed in brilliance or effect. Under the roof of the colonnade, on one side of the main entrance, are powerful but invisible electric lights which illuminate the frescos, and these, forming distant pictures among the statuary and myriads of coloured lights, add greatly to the general decoration in which the central figure is the stately Grand Palais itself, with its glass roof glowing against the dark sky. Dense crowds entering and leaving the Salon, and a ceaseless stream of vehicular traffic of every description, give the necessary air of life en fête to this imposing scene.

Coupe Rothschild. In addition to these, there is the Rochet-Schneider car, which figured at the Brighton meeting, the Cottureau racer, previously mentioned, and another less powerful machine on the Brouhot stall. Messrs. Mendelssohn exhibit a racing voiturette of 55-h.p., which weighs only 380 kilogs. On this machine, there is practically nothing but the engine and the four wheels, and even the differential itself on the live axle is exposed—a more dangerous-looking machine we have seldom seen exhibited anywhere.

Unorthodox Cars.

Although this year has brought out remarkably few unorthodox cars there are, nevertheless, quite a number of these on the market, and several of them have established a very enviable reputation for themselves as

there is the famous De Dion, which is so well known that its peculiar rear axle arrangement has long ceased to be a matter for comment. Among special change-speed-gears there is the Pilain, which has every speed a direct drive, and obtains this by a series of three different-sized bevel wheels on the rear axle. These permanently mesh with their respective pinions, which are solid with the propeller-shaft, and the speeds are obtained by locking either one of the bevel-wheels to the live-axle. On the Henriot car, the gear itself is not peculiar, but the gear-box is formed as part of the back-axle casing, while on the Motobloc chassis it is combined with the crank-chamber. In the gear-box on the Cornilleau and Sainte Beuve chassis, the gears are arranged on the Mercedes principle, but with this difference, that the sliding sleeves are free on their own shafts

THE PARIS SALON.—View of an automatic tyre pump fitted to a Bollée Chassis. The pump cylinder, A, is formed with a crank-chamber, A', containing a gear-wheel which meshes with a pinion on the main-shaft, just in front of the gear-box. In the photograph the flexible tube, A'', is shown connected to the pump ready for inflating the tyre.

until after the wheels are partly in mesh, when the final movement locks them in place by a loose jaw coupling. The idea is, of course, to simplify the action of changing speed by reducing to a minimum the weight of one revolving part. Last year the engine on this car had some peculiar features, but these have now been modified and others added. All the valves and igniters are operated by the same cam-shaft and the rods are enclosed behind inspection-covers. The igniters, too, are very peculiar, for the vertical rod itself passes into the inlet-valve-chamber, and terminates in a large scythe-shaped contact-arm, which passes all round the valve to reach the "live" contact. This arm lies horizontally, and the igniter rods obtain their slight rotary motion from face cams on the cam-shaft. Very large inspection-covers are fitted above the valves, and through these the igniters can be withdrawn when necessary. Among other special engines which were shown for the first time last year, and are again on exhibition, is the double-acting Rene

Legros, which we described at the time. The Luc Court chassis is also again on view, this being constructed, it will be remembered, so that the rear portion can be removed complete with the body and the front part, recoupled up again to another rear section mounted with a different body, the object being to facilitate the interchange of various bodies of different sizes.

Voiturettes.

There are quite a number of little two-seated cars at the Salon this year, but it cannot be said that many of them offer any remarkable attractions, or are worthy of classification among such cars as the 6-h.p. Wolseley. The majority are little live-axle machines, with tiny spindles for propeller-shafts and diminutive engines and gear-boxes mounted on rather rickety underframes. In fact, not a few of them look as if they might collapse if they were trodden

on. One or two makers, as usual, display a startling disregard for orthodox principles by adopting some more or less ingenious novelty in the design. There is the Sizaire and Naudin, for instance, which has a three-speed gear, in which every speed is direct. This is obtained by mounting three pinions on the propeller-shaft and engaging them in turn with a single, large, facial, toothed wheel on the rear axle. We have not yet had an opportunity of inspecting the shape of the teeth, but it is to be presumed that those on the big wheel are of an unusual form. In some other points the simplicity of the chassis construction is worthy of attention. It has a wood frame suspended on projecting leaf-springs at the rear, and on a single transverse spring in front. The front axle actually forms part of the frame, and the vertical steering-heads pass freely through the bosses at each end; it is on their projecting ends that the tips of the inverted transverse spring—which is tied to the axle at its centre—are allowed to rest. A single-disc clutch transmits the power from the engine to the

THE PARIS SALON.—The Auto-Mixte Chassis, in which a dynamo and battery, B, are used as a substitute for the change-speed-gear. Immediately behind the dynamo is the magnetic clutch and brake. A disc is keyed to the propeller shaft and is clutched, magnetically, to the engine shaft when driving, and to a stationary member when retarding.

THE PARIS SALON.—A De Dietrich *Berline de Route*, which has the small double seat behind protected by a neat hood. It is a very handsome carriage and is particularly suitable for those who wish to take their own servants and luggage with them when touring.

propeller-shaft. Of quite a different type is the little S.V.P. car, which has the rear wheels carried by a stationary axle, and driven through spur-gearing from a transverse countershaft. This countershaft is divided, but has no differential; instead, it is driven by a belt which bridges the divided pulley, so that if one half wants to go faster, or slower, than the other it has to slip under the belt. The belt passes the full length of the chassis to a gear-box, which adjoins the crank-chamber. Two speeds are available by the sliding-spur-wheel-gear, and the declutching is obtained by swinging over the gear-box bodily until the belt is slack.

Mention might also be made of the Guy voiturette, which has a 4-cylinder engine of only 7-h.p. It is air cooled, its power is transmitted through a fibre-faced cone-clutch and a cardan-shaft to a live-rear-axle. Then, also, there is the surprising little Otav, which has a single-cylinder engine driving a countershaft by a chain, and the rear wheels driven by side belts.

Electric Vehicles.

Curiously enough, electric cars are quite a feature of the Exhibition—of course, comparatively speaking. Among the exhibitors were Vedrine, Jeantaud, Krieger, Columbia, Gallia, Dinin, Milde, Electromotion, Cardinet, and Zeddeco. Some of these names are already famous, and most of them are well-known in connection with accumulator manufacture, even if they have not previously been associated with actual cars. In general, of course, the cars are purely town carriages, although, for the most part, their design seems less graceful than that of those to which we are accustomed in London. In some cases, however, there was an obvious anxiety to copy the modern touring car, but whether with an eye to the possibilities of the bonnet as a storage place for bulky batteries, or whether with a view to meeting a genuine demand for this form of vehicle, it is im-

possible to say. Of course, the accumulators are in each case ultra-Edisonian in their vaunted capabilities, but notwithstanding the imposing exhibits there is no real sign that the electric vehicle has as yet outgrown its legitimate limits of use as a desirable town vehicle for high-class society. Without going into detail about the various systems, it is interesting to note the variety in the transmission adopted in each case, since it offers a strong contrast to modern practice in petrol cars. Vedrine and Dinin cars have a live-rear-axle driven through spur-gearing by a single motor mounted upon it. Jeantaud drives in a similar manner on the front axle. Krieger has a motor against each front wheel and a drive to each through internal gearing. Columbia and Gallia vehicles are similarly driven on the rear wheels, except the little runabouts, made by the former company, which have a single chain to drive the live-axle. Milde employs a single motor and a cardan-shaft; Cardinet does the same, but this car has the motor under the bonnet and the shaft is driven by a chain. Electromotion cars have motors enclosed inside each of the rear wheels, while the Zeddeco cars have a similar system applied to the front wheels. In this latter case, Lohner motors are used, similar to those described in our issue of April 4th, 1903.

(To be continued.)

THE PARIS SALON.—View of the automatic starting device on a Renault Chassis. A toothed wheel is mounted on the periphery of the fly-wheel and with this engages a small pinion driven by a three-cylinder compressed air engine, A. The compressed air is carried in a cylinder attached to the frame, and can be maintained by opening a valve communicating with the cylinders of the main petrol engine. Provision is, of course, made for throwing the starting device out of gear when the engine has been started.

MOTOR VOLUNTEER CORPS.

(Officially Communicated.)

THE 31st October brought to a close the third volunteer year since the formation of the Motor Volunteer Corps, and it has on the whole been most successful.

The efficiency of the corps has been well maintained, and the readiness invariably displayed by its officers and members to accept duty, although often at extremely short notice, is evidence that the right spirit is predominant, and so long as this spirit exists continued success may be looked for.

The whole of the staff tours carried out by the regular forces have been performed by the aid of the Motor Volunteer Corps, and the Generals Commanding-in-Chief have testified in every way to the high state of efficiency and utility attained, which high opinion has been confirmed by H.R.H. the Duke of Connaught, Inspector-General of the Forces, and by the Chief of the General Staff.

Very varied has been the nature of the duties performed, amongst which have been royal visits, royal reviews, staff tours, signalling operations (long distance), recruiting tours, tactical examinations, manœuvres, &c., &c., and it is highly creditable that in every case the demands of the military authorities were complied with, notwithstanding the fact that in many instances less than 24 hours' notice was given to the commanding officer.

By command of His Majesty the King a strong detachment appeared at the Royal Review, held at Aldershot, on the occasion of the visit of the King of Spain, and the Scottish Sub-command was present at the recent Royal Review of the Scottish Volunteers.

During the year 124 duties were performed, which occupied no less than 1,321 days.

Taking the strength of the corps during the year, *i.e.*, 159, all ranks, an average of 10'18 days' duty was performed by each officer and member.

The total distance travelled on duty by cars was 87,941 miles, and by cycles 10,338 miles, being an average of 814'26 miles per car and 516'90 miles per cycle during the year, and 75'42 miles per car, and 74'91 miles per cycle for each day employed.

Excluding the capitation grant paid by the Government to the corps, the cost to the public for the use of the motors has been approximately 5*d.* per mile for cars, and 1*½d.* per mile for cycles.

Owing to the fact that no general manœuvres took place during the past year a few of the cyclists were without employment, which is to be regretted, but it is hoped that during the coming year extensive army manœuvres will take place, when the cyclist members will be able to repeat the useful service performed by them in 1904 in Essex, when they travelled over 17,000 miles, and won golden opinions from every general officer employed in those operations.

The few instances of breaks-down whilst on duty were of such an obviously unpreventable description, being in all cases due to those misfortunes which the best conducted motor cars are heirs to, that they speak volumes for the excellence of the cars placed at their country's service by the gentlemen of the corps.

Considering all things, therefore, it must be admitted that the Motor Volunteer Corps has gained much honour and credit during the volunteer year which has just ended, and Colonel Mayhew has every reason to be proud of his command.

Impressive Figures.—As the Royal Commission on the Motor Car Acts is still engaged on its labours, no opportunity should be lost of drawing attention to the great and growing importance of automobile manufactures for the well being of this country. We embrace the opportunity therefore afforded by the recent utterances of the French Minister of Commerce to bring the figures relative to the French export trade, which we have previously published, up to date. They are as follows, for the years since 1897 :—

Francs.			Francs.		
1897	...	623,000	1901	...	15,782,000
1898	...	1,649,000	1902	...	30,219,000
1899	...	4,259,000	1903	...	50,837,000
1900	...	9,417,000	1904	...	71,302,000

The Minister of Commerce further estimates that the value of the automobile exports from the Republic from the year 1905 will total at least one hundred million francs. It must be borne in mind that Great Britain (as universally recognised on the other side of the Channel) is the best customer that the French automobile manufacturers possess, and that the great bulk of the exports, probably about three-quarters of them, find their way to Great Britain. No more eloquent testimony of the great and growing importance of the automobile industry for this country need be asked for. In addition to the enormous number of cars and accessories manufactured at home, increasing as it does by leaps and bounds every month, the English market still requires the importation of this enormous supply of automobiles from France alone, without taking into account the very large additions from Germany and the United States. From the latter country, the exports—which are now for the first time published separately for each country—are by no means negligible either, and from them it can now be ascertained that in this case also Great Britain is the best customer. Adding to the amount exported to the British Islands those exported from the U.S.A. to other British possessions, notably British North America, it will be seen that upwards of one half of the total automobile exports from the United States find their way into the hands of British purchasers. The actual values are as follows :—

			October.	10 months.
United Kingdom	\$50,136	\$604,782
France	2,190	254,030
Germany	8,162	101,998
Italy	1,740	154,325
Other Europe	8,903	222,817
British North America	18,715	501,765
Mexico	13,404	150,042
Other West Indies and Bermuda	12,274	124,552
South America	5,571	48,938
British East India	3,620	28,602
British Australasia	4,043	85,548
Other Asia and Oceania	1,318	60,591
Africa	2,716	28,737
Other Countries	1,136	2,894
Totals	\$133,988	\$2,369,621

French Official Records.—Owing to the many questions which have arisen in connection with records on the Arles-Salon road, the A.C. de France have issued a statement governing official records for the future. Records on this road may be made over 1, 5, and 10 kiloms., between the 59th and 49th kilometre points. Commencing from January 1st, the club notify that in order to prevent possible irregularities due to individual organisation and lax control, records will not be officially recorded unless they are established in open and public trials authorised by the A.C. de France.

THE NEW ARROL-JOHNSTON PETROL CARS.—PART VI.

Fig. 24.—The Arrol-Johnston Steering-gear, one of the special features of which is the adjustment-screw, Q^7 , for taking up back-lash. Views showing it both complete and in parts.

The Brakes.

AN exceptionally good type of brake has been devised for these cars, for not only is it powerful though "soft"

the bottom as well as at the top. Their lower ends nearly meet about the same fulcrum-pin, and are only held together about that pin by the collars, P^2 , that encircle the projecting bosses.

For holding the shoes clear of the brake-drum, there are two strong springs, P^3 , arranged as seen in Fig. 21, and, for forcing them apart, there is a simple lever-mechanism operated by the rod, P^4 . Passing through one of the two levers that actually engage with the brake-shoes is an easily accessible set-screw, P^5 , that alone provides for all necessary adjustment, and this set-screw has a nut by which it may be locked when readjusted.

The Steering-Gear.

Special care has been taken in the design of the Arrol-Johnston steering-gear, to prevent the threads of the worm and nut from wearing unequally, and to provide a ready means by which any wear that does occur can be easily taken up. With these

objects in view, the doubled-threaded worm, Q , is made sufficiently long to accommodate the nut, Q^1 , at all times, and this nut, which is made in two separate parts, has a slight space left between the two portions. Each

part has projections, upon which ride the curved bearing-pieces, Q^2 , these pieces being held in place by the encircling arms, Q^4 and Q^5 .

The nut, Q^1 , itself is, of course, prevented—by machined faces—from turning round inside the oil-tight casing, and the arms, Q^4 and Q^5 , are carried by the rock-shaft, Q^3 . One pair of arms, Q^4 , is fixed rigidly to the shaft, Q^3 , but the other pair, Q^5 , rides freely about it. Both sets have, however, other projections by which they can be forced up together, scissor fashion, and made to grip the bearing-pieces, Q^2 . For this purpose, holes are drilled through the shorter projections of each of the arms, Q^3 , and into these holes fit the ends of the yoke-bar, Q^6 . Through the yoke-bar is a bolt with a spring-washer beneath its nut, and this bolt passes through the corresponding hole in the arms, Q^4 .

When the steering-gear is fixed in place, the inspection-cap, Q^2 , is readily accessible at the top of the casing, and, since the nut, Q^1 , lies just inside the cap, it is easy to tighten it at any time. The effect of tightening it is to draw the arms, Q^4 and Q^5 , closer up together, and also to force the two halves of the nut, Q^1 , more tightly up against the threads of the worm, Q .

On both sides of the worm, Q , are ball-thrust collars, the upper of these being adjustable to take up all end play. The worm itself and the steering-pillar are hollow, and inside them are a sleeve, R^1 , for holding the quadrant, R^2 , and a smaller tube, R , to which is fixed the engine-controlling lever, R^3 . It is this smaller tube that also serves to connect the rubber bulb above the steering-wheel with the hooter. In Fig. 24, the ball-and-socket joints, and the tube, that connect the steering-gear with the lever-arms on the front-axle, are shown lying beneath the parts with which we have just been dealing, and so, too, are the lever-arms themselves. In Fig. 25, the construction is shown partly by sectional drawings and partly in elevation.

Concluding Remarks.

From the particulars which we have now given, concerning the construction of the new Arrol-Johnston cars, it will have been evident that, even down to the most

minute detail, their design has been the result of most careful study and consideration on the part of Mr. J. S. Napier and his assistant staff of engineers. We have, too, laid special emphasis on the fact that every care, and a considerable amount of unusually expert knowledge, has been brought to bear on the selection of the most suitable grades of material from which to make each and every individual part, and that all the most up-to-date methods of manufacture—in large interchangeable quantities—have been adopted in the Paisley works. It only remains, therefore, to say a few words about the actual capabilities and qualities of the new cars which are now being turned out, and naturally our readers will take an even greater interest, from this point of view, in the horizontal type of car—the 12-15-h.p. model—than in the larger and more orthodox 4-cylinder vehicle.

We have ourselves, during the past few weeks, been using one of the Tourist Trophy cars, and have already driven it a considerable distance both in the traffic and in the open country, with the result that we are able to speak from practical experience of the many undoubted merits of this type of vehicle. Although only finished off primarily with a view to running in the race, we have found it an exceptionally comfortable car, and one that is extremely handy for all-round general work. Geared somewhat high—as is this particular car—in comparison with most vehicles of similar power (18-h.p.), it yet lends itself well for travelling quite slowly, or for restarting in traffic, on the top gear, and nothing more could be desired as regards hill-climbing. So far as the engine is concerned, it may be said that we know of no other twin-cylinder petrol engine that runs more smoothly or takes to its work more kindly, while the absolutely automatic nature of the lubricating system, and the freedom from risk of smoke issuing with the exhaust gases, are most satisfactory features. Mention should, moreover, be made both of the remarkable facility with which changes can be made from any one "speed" to another—this being but one merit of the special form of clutch employed—and of the extremely effective brakes, which are well calculated to give confidence on any hill, however steep.

“DIRECT-DRIVE”—IS IT A MONOPOLY?

It does sometimes happen—and the very nature of the Patent Laws renders it ever possible—that after everyone has become accustomed to the unrestricted use of some particular type of mechanism, it is suddenly found to be a patented invention. So far, it is of course impossible to express any definite opinion as to whether this is now the case with the “direct-drive,” that forms so familiar a feature of most modern petrol vehicles, but it appears that the celebrated Renault firm of automobile builders in France, are at least considering the extent to which they hold the exclusive rights to use it. Such an enormous number of cars—and indeed the majority of makers—now employ the “direct-drive” system for transmitting the power straight through the gear-box, to give the top “speed,” that the question is one of no small moment to all motorists, for there is, at least, the matter of possible royalty to be considered.

According to a French contemporary, the Renault Company base their claims on a patent taken out in France on February 9th, 1899, but it would, of course, only be the corresponding English patent that would affect motorists in this country. Apparently the English patent in question is that of Louis Renault, dated the 22nd February of the same year, and this bears the number 3981. Much obviously depends upon possible anticipation by other users or inventors, but in view of the interest which is sure to be taken in the patent, we

alone, indicate that a “direct-drive” could be obtained straight through the gear-box, B, from the clutch, A, to the bevel-pinion, E, and that in general respects the arrangement is like that now employed on most live-axle vehicles.

In Fig. 3 there are four drawings that indicate the construction of the gear-box, those on the right being a plan (with the top of the box taken off), and a vertical section through the box, with the “through” shaft in elevation. On the left, the upper drawing is another vertical section, but in this case it is the lay-shaft, J—that which is used for the first speed and for the “reverse”—of which a side elevation is given. The remaining drawing is a front elevation of the gear-box, and this gives a good idea of the positions occupied by the operative and the operating shafts.

Very little explanation need be given, except that there are two lay-shafts (J and K), and that both are mounted eccentrically in their bearings to enable their gear-wheels to be brought into mesh laterally—instead of by a sliding motion—with those on the “through” shaft. The chief feature, of course, is that the “through” shaft is made in two parts, L and M,

which are locked together by the jaw-clutch, N, when the third speed is wanted. For this purpose the wheel, L'—together with one portion of the jaw-clutch, N, is rendered free to slide on the shaft, L, but is normally—when running—locked to the shaft, M, by virtue of the spring, N¹; this sliding member is moved forward, against the action of the spring, N¹, by the fork, G¹, to throw the third speed out of action.

The two wheels, M¹ and M², are used, respectively, in conjunction with the lay-shafts, J and K, for they correspond with the spur-wheels, J¹ and K¹, on those shafts, in just the same way that the other spur-wheels, J² and K², correspond with the wheel L¹. For the first speed the lay-shaft, J, is thrown inwards by its eccentric bearings to bring its wheels into mesh with those on the interrupted “through” shaft, and similarly the second speed is obtained by bringing the lay-shaft, K, up towards the “through” shaft. One or other of them then constitute a bridge, through which the power is transmitted, the gear-ratios of the four spur-wheels for each “train” being suitably proportioned to give the required result.

Precisely how the lay-shafts are controlled by the mechanism, G, is relatively unimportant, but a word of explanation concerning the “reverse” gear is, we think, needed. Mounted on the lay-shaft, J, are two facing bevel-wheels, J³ and J⁴, while between them is a jaw-

Figs. 1 and 2.—Side elevation and plan (partly sectional) showing the general arrangement of the Renault main-clutch, gear-box, propeller-shaft, and live axle, specified in Patent No. 3981 of 1899.

now give a *résumé* of the specification, together with the “claims” and some of the attendant drawings. Even apart from any likelihood of forcible action being taken by the owners of the patent, the invention itself is well worthy of notice, for it at least—apart from other considerations—brings home the remarkable progress of the industry during the past seven years.

Figs. 1 and 2 are more or less diagrammatic, and are partly sectional, being a side elevation and a plan, respectively, of the clutch, A (with its retarding brake-ring, A¹), the gear-box, B (with the foot-brake, C, just behind it), the propeller-shaft, D (with universal joints, D¹, at each end), the bevel-pinion, F, and the bevel-wheel, E, on the “live” rear-axle. Fig. 1 also shows the somewhat complicated gear, G, for operating the three forward “speeds” from the steering-pillar, and the curious little pedal, H, (in the top of the gear-box) for bringing the “reverse” bevel into engagement. These drawings,

clutch that "breaks" the shaft into two independent elements in just the same way that the "through" shaft is "broken" by the jaw-clutch, N. Normally the spring, H¹, keeps the sliding bevel-wheel, J³, locked direct to the bevel-wheel, J⁴, but arranged above them is an intermediate bevel-wheel, H², carried by the "reverse" pedal, H. When the pedal is depressed, the bevel-wheel, H², forces the wheel, J³, away from the wheel, J⁴, and brings itself into mesh with both of them. The rear portion of the shaft, J, is thus caused to revolve in the opposite direction to the front portion, and consequently the car is driven slowly backwards, if the wheels, L¹, J², J¹, and M¹, are also in engagement with one another. The following are the "claims" made by the inventor in his English patent:—

1. An improved driving and speed-changing mechanism for motor vehicles, characterised by the fact that the movement is transmitted from the motor to the driving-wheels directly by gear-wheels without the medium of chains or belts, though the motor and the speed-changing mechanism be supported on springs, and capable of being moved independently from the wheels, the said mechanism comprising moreover the above described peculiar devices enabling the movement to be transmitted through two gear-wheels only, and the changes of speed to be effected while reducing the friction to a minimum, substantially as and for the purposes specified.

2. In gearing for motor vehicles, the combination of friction-clutch mechanism forming a coupling, a brake working with one section of the coupling, means for actuating the brake and coupling in unison, and means for transmitting the movement of the coupling section with which the brake is connected.

3. In gearing for motor vehicles, the combination of clutch and brake mechanisms, a toothed wheel, and a shaft connecting the clutch and brake mechanisms with the toothed wheel, the connections of the shaft being such as to permit the independent play of the clutch and brake mechanism with respect to the toothed wheel.

4. A gearing for motor vehicles, the gearing being arranged in two sections, and a shaft connecting the sections, the connections being such as to permit the independent movement of the several sections of the gearing.

5. In a gearing for motor vehicles, the combination of a primary movement member driven from the motor, a clutch working with said member, a shaft driven by the clutch, the shaft being in two sections with a releasable connection between them, variable speed-

Fig. 3.—Four drawings of the 1899 Renault gear-box. On the right, is a side elevation of the central "through" shaft—the gear-box being shown in section; above it, is a plan of the gear-shafts with their gear-wheels; on the left, is a front elevation of the gear-box, and above that drawing is a side elevation of the first speed and "reverse" lay-shaft with the casing in section.

gear for driving the sections of the shaft, and movement-transmitting devices in connection with said shaft.

6. The combination of a shaft formed in two sections, a clutch connecting the sections with each other, an eccentrically-mounted shaft, movable eccentrically toward and from the first-named shaft, gears fastened to the several shafts, and means for operating the clutch and for throwing the eccentric shaft in unison with each other.

7. The combination with a casing, of a shaft mounted thereon and formed in two sections, a clutch connecting the sections, a shaft mounted in the casing, means in connection with the shaft for throwing the clutch, a third shaft eccentrically mounted in the casing and movable toward and from the first-named shaft, gear-wheels attached to the first-named shaft and to the eccentric-shaft, and means for throwing said eccentric-shaft, such means having connection with the second-named shaft.

Of these claims, it is No. 5 that obviously attracts most attention, though Nos. 1 and 4 also bear upon the "direct-drive" arrangement as used to-day.

WHEN your memory becomes a blank, from excessive indulgence in C₂H₅O or any other cause, creditable or otherwise, and you subsequently find yourself in the witness box, do not make any definite statement on oath as to what occurred during the mnemonical blank. This self-evident precept was neglected by Mr. H. A. Routh, of Leeds, in last July, with the result that he has now been ordered six weeks' imprisonment in the second division for perjury. In the early part of July last Mr. Routh was prosecuted for driving through North Street, Leeds, with his tail lamp out. Giving evidence in his own behalf, he swore that he was not in North Street at the time in question. It was subsequently, however, proved both that Mr. Routh was in North Street at the time the policeman alleged, and that he had been merry-making with such effect that he had no recollection whatever of what transpired after he betook himself to the Queen's Hotel, but was under the

impression that he had spent the whole of the night in that hostelry. The judge made some very severe remarks, and inflicted on Mr. Routh the sentence we have alluded to above. The punishment, it must be admitted, is, for perjury, a light one, and it was probably mitigated by the judge's doubt, in spite of his one-sided summing-up, as to whether real perjury had been committed, for it would certainly appear that Mr. Routh at the time he gave his evidence honestly believed it to be true.

IN order to render motoring in the desert possible, two American inventors have devised a special tyre, which consists of sandbags strapped on each side of an ordinary pneumatic tyre. This is homœopathic treatment, or tackling like with like, with a vengeance. Contemporaneously, two other American inventors have devised a special desert.

CORRESPONDENCE.

* * *The name and address of the writer (not necessarily for publication) MUST in all cases accompany letters intended for insertion, or containing queries.*

SPRING WHEELS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Mr. Clifford Hallé, in his letter appearing in your columns, says I seem to have convinced myself that the movement of the axle of a spring wheel relatively to the rim causes a change of gear, my letter had not been despatched long when I saw the error of this reasoning, but this does not affect my views on the subject as a whole. The effect, although driving out of the centre, is just the same as an ordinary wheel as far as gearing is concerned, only in the case of the axle being out of the centre, in a driving-spring-wheel the power is conveyed through the centre but at a point away from it. For in both cases an equal distance would be travelled with one turn of the hub or axle, even in the case of the axle being pressed out of the centre during the whole revolution of a spring wheel.

With reference to the correct place for the springs to be fitted, namely, between the car body and axle, hub and rim or a combination of both, time should tell, and it is only by practical experiments in a great many instances that the real truth can be arrived at. Should there be commercial advantages to be gained by using spring wheels, then I wish the inventors the success they deserve.

Wandsworth.

A. V. ROE.

ORGAN-PATTERN FOOT-PEDALS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Steel foot-pedals for motor cars are now almost universal, some of which are of very solid construction, consequently after driving a few miles in winter time one's feet are apt to get cold, and more so when there is not much chance to remove the feet from the pedals.

I have recently been trying pedals of the organ type, and find them a great comfort after the steel pedals, then again they can be fitted with removable thick felt mats or some non-conductive material, or, to carry the point of comfort still further, boot muffs can be fitted on them.

Some people prefer the "push" pedals, while others the "press down," but the organ type has the advantages of both, as neither is the heel slipping on the footboards or the feet on the pedals.

Yours faithfully,

A. V. ROE.

DANGEROUS ROADS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Will you kindly allow me the hospitality of your columns to strongly protest against the dangerous state of the stretch of road between "The Bell," Hounslow, and Hounslow Barracks. I happened to be passing through this neighbourhood a day or so ago, and was driving my car partly on the tram lines and partly on the macadam. Overtaking a small van, I naturally endeavoured to steer the wheels, which were on the concrete, across the tram lines, in order to pass the vehicle, but owing to the macadam being, in places, three inches below the tramway track, I was unable to do this, with the result that the wheels skidded, the car running into the van, doing considerable damage.

I should certainly advise your readers to use any other route than this until the roads are improved, as the present condition of the thoroughfare in this district is positively suicidal, not only to motorists, but to all other users of the road. It is noteworthy that the Tramway Corporation and District Council repudiate any liability when accidents occur.

Yours faithfully,

Kensington, Dec. 12.

W. H. ARNOLD.

THE TOURIST TROPHY REGULATIONS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I am in receipt of the final Regulations for next year's contest, and observe with much surprise that petroleum spirit only is to be permitted, and that the allowance for both petrol and steam cars is to be one gallon for every 25 miles. Therefore, steam cars are, to all intents and purposes, debarred from competing; the Turner-Miesse and Serpollet absolutely, for they use paraffin, not petroleum spirit.

It is obvious, therefore, that the letters of Messrs. Claude Johnson, S. F. Edge, C. S. Rolls, &c.—all directly interested in the manufacture of petrol cars—have had undue weight with the Committee of the A.C.G.B.I., who, after recommending such a basis as would give steam cars at least a sporting chance, have now performed a

complete "volte face," and have precluded the possibility of any steam car successfully competing, and prevent the Turner-Miesse and Serpollet competing at all.

Is it to be wondered at that the advocates of steam cars should smart under a sense of gross injustice? It is entirely contrary to the British idea of sport, that because certain manufacturers and those interested in petrol cars, have an uneasy idea of the possibility of a steam car winning the Trophy, that no steam or other car using a cheap fuel such as paraffin shall be allowed to enter.

It may be business on the part of those interested in the manufacture of petrol cars, but it certainly is not sport. Any unprejudiced person will admit that every encouragement should probably be given to those firms who are seeking to find a satisfactory and cheaper substitute for petrol, which is bound to increase in price in the near future.

Is this barring of steam cars to be the rule all over again in the case of Hill-Climbs and Speed Contests next year? I had hoped otherwise. If such is the case, the public ought surely to consider it the best testimony to the merits of the steam car that the advocates thereof could ask for.

The Frenchman gives steam its chance, and allows Serpollet to compete; in America the White and Stanley have a fair field; but in England the position taken up by the Committee of the A.C.G.B.I.—an Institution presumably founded for the encouragement of the industry as a whole, and not purely to protect the interests of petrol car manufacturers—appears to be that lest perchance a steam car should win, we will either bar it altogether or make the conditions impossible for it to successfully compete.

I think an explanation from the Committee of the A.C.G.B.I. as to the reasons which caused them to disregard the suggestions of their Technical Committee (who recommended regulations which would have given steam cars a sporting chance in 1906) would be received with interest by motorists generally.

It would also be convenient if the A.C.G.B.I. would state if they intend to bar Turner-Miesse, Serpollet, White, Stanley, and other steam cars from the competitions held under their rules during 1906, and their reasons why it would be unfair to the petrol car to permit the steam cars to show what they can do alongside petrol cars of the same price.

Yours truly,

Wolverhampton, Dec. 15th.

J. BURNS-DUMBELL.

P.S.—I observe since writing above that a protest was received from the Society of Motor Manufacturers against the proposed regulations permitting steam cars to compete. The public, therefore, ought to appreciate the fact that it is the manufacturers of petrol cars, and to a great extent the English agents of foreign built petrol cars, whose bias has been permitted to outweigh the regulations suggested by the Technical Committee of the A.C.G.B.I.

Is it fair to steam that rival manufacturers should be allowed to decide the matter?

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—“Fair field and no favour” is the wish (or supposed to be) of every British sportsman, no matter what the line may be. I think this spirit might be applied to the present vexed steam petrol question without a great amount of difficulty. So far as I can gather a brief summary of the position is—

Petrol car objects to steam having a larger allowance of fuel per mile than allowed to petrol car.

Steam car says, I ought to have about *twice* the amount of fuel as I can run on paraffin which is half the price.

For the sake of a basis, I think we might take paraffin actually as half price, as although paraffin is really cheaper than this at present, it is not on fair valuation, but owing to temporary fierce competition between the oil companies.

Against this, in the case of the steam car, we must put the disadvantage of having to carry twice as much fuel or fill the tanks twice as often, and the fact that paraffin is disagreeable, dirty, smelly stuff to handle, and liable to get wherever not required and stay there, whereas petrol is clean to handle and if spilled soon evaporates.

Paraffin, it is claimed, can be obtained almost anywhere, but I don't think this is much in its favour in this country, but it is worthy of consideration when motor vehicles are shipped abroad.

Now, I take it, the T.T. Race is for the improvement of motor vehicles and not for sport (more's the pity), and as reduction in running expenses is a very important improvement, especially as applied to commercial vehicles, paraffin, in spite of its disagreeable qualities, ought to be given at any rate a “fair field.”

I would suggest that the Committee dealing with the T.T. Race should carefully consider all the pros and cons of paraffin and petrol respectively, and then quote an optional allowance based on the present 25 miles per gallon (petrol), allowing 16, 18, 20 or more

miles to the gallon, as the case may be, if paraffin be used, the rule to apply equally to steam and internal combustion motors.

Under these conditions, I do not think either party would have cause for complaint provided the rule regarding this be published at once in order to give manufacturers time to experiment with and perfect paraffin carburettors and burners.

Should the Committee not find (as I expect they would) that the disadvantages of paraffin quite outbalance its advantage in cost, then in the actual race every car would start *cold*, that is to say, no time would be allowed for lighting burners or heating carburettors, &c., and time so occupied would count as running time.

Yours faithfully,

ERNEST H. ARNOTT.

Teddington, Dec. 16th.

AN IMPRESSION OF THE PARIS SALON AND OLYMPIA.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Never was it easier after a visit to Paris to set down one's impression of the Automobile Salon of the year. In years past I have been bewildered with a number of ideas which were harder to formulate than to put down when formulated, but this year all is changed. The lessons to be learned are few, simple and easy to appreciate.

Just one word for the Exhibition as a sight. Never before in the history of Exhibitions has been seen a picture so beautiful or so grand as the view from the gallery of the Grand Palais in the evening when all the lamps were alight, and the roof and dome of the building were one mass of colour and splendour. We may decrate Olympia, but never can we hope to produce so fair a picture as that of the 1905 Salon. Expense alone would present a difficulty. I was informed that the general illumination of the building costs £300 per hour when all the lights were lighted. The stands also seemed to be, taken as a whole, much finer than last year—an indication of the strenuous competition which each year grows keener and keener. Artistic to the last degree and brilliantly lighted, they were examples par excellence of the exquisite taste of the French as a nation, and as a last word of praise I may say that, as a spectacle alone, the Exhibition was well worth visiting. And then as to constructional tendencies, I looked eagerly for any particular "following" ideas, but I found none. No *clou*, no extraordinary principle, no new gospel. Even the threatened 6-cylinder boom was conspicuous by its absence. (I only discovered one French manufacturer exhibiting a 6-cylinder chassis, and he was not one of the big *marques*). Yet, in spite of this lack of sensation, there has nevertheless been a splendid year of progress in construction and design, and this was evidenced in the Exhibition—a levelling up of a number of makes, better finish, and a care and attention to detail never before known. Particularly was this noticeable in connection with the exhibits of the best known old leading firms. Simplicity in design was noticeably present where before it was noticeably absent. Attention has been paid to ease of control and silent running, and particular attention has been paid to comfortable suspension, and these many important advantages are not secured at the expense of simplicity. Magneto ignition, either low or high tension, now seems to be almost universally adopted by every firm of note, and lubrication fittings have been considerably simplified. No one appears to have decided which is the most graceful and effective shape for the radiator, and in consequence every possible size, shape and form of construction is in evidence. Push pedals are universal, but no one seems to agree as to whether the side brakes should be "push on" or "pull on."

Chassis are all on the long side, necessitated by the roomy and luxurious carriage bodies now generally fitted, and on this point there is no question but that this is the year of the big closed-in car, and I think I might say that nine out of every ten cars shown, sold and used outside the Salon were of this type.

I was, frankly speaking, disappointed at the display of French carriage building this year, which did not, in my opinion, reach the standard of excellence shown at last year's Exhibition, whilst our own Olympia Exhibition was far away ahead of this year's Paris Show in displaying excellently finished and soundly constructed carriage bodies—both open and shut.

And now as to business done, there was quite a different story, when I left Paris, to that told at Olympia. Obviously the big firms were not affected, as their output for the year was sold prior to the Exposition, but as one disconsolate trader said to me, "We always expect to book a number of orders from Englishmen, but your Show being before ours has prevented their coming over this year," and consequently the dearth of English buyers has been considerably felt. This is as it should be. All those who are interested in the sale of cars in England, whether of foreign or English construction, must admit that it is much more satisfactory to do one's business

in England than to have to travel to France for the purpose. I must frankly admit that I considered the date of the English Show in November ill advised, and I still think that the risk of fog and bad weather—which would affect the success of the Exhibition very considerably—is very great, but after the experience I have gained this year at Olympia, and the information I have gleaned in Paris, I certainly consider that importers and English manufacturers should join hands solidly to secure the holding of the English Show prior to the one held in Paris, and thus make England the one great buying and selling centre in the automobile world of all makes of cars.

Yours faithfully,

Dec. 16th.

CHAS. JARROTT.

REGISTER OF POLICE CASES.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Will motorists and sympathisers kindly send us particulars of any motor car case within their knowledge where the police evidence has been successfully disproved. Our recent victory, of course, need not be included. We intend to compile and keep up to date a register which will be of the greatest benefit to every automobilist suffering, or likely to suffer, from an unjust prosecution.

Press cuttings from the agencies, however useful, are not sufficient for the purpose. We require a short account from one's personal recollection, together with, if possible, the name, rank, division, and number of the veracious constable in question, and a cutting from the paper which gave the fullest report. If you, Sir, will kindly influence the completion of what I can assure you is a sound practical scheme, every motor car driver summoned in respect of speed limit or alleged furious driving shall have the opportunity of learning from our register if his particular accuser has "any endorsement on his licence."

Like other schemes for the good of the community, it involves the trouble of a few minutes' search on the part of each interested motorist, but the value of such a record is obvious. This perjury farce shall be played out.

I am, Sir,

Your obedient servant,

STENSON COOKE,

18, Fleet Street, E.C.

Secretary, The Automobile Association.

THE SHOW QUESTION.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—On the question of separate shows for commercial and private passenger cars, we are very strongly of opinion that the time has come to hold two distinct shows, if indeed it had not already arrived before the recent Olympia Show was held.

We understand that over 150 firms were crowded out, and many well-known firms had to put up with totally inadequate space in both sections.

The number of firms now building commercial cars is quite sufficient to make a separate show a success in every way, and it must be remembered that the two classes of goods are purchased by very different types of buyers who would only be interested in the one kind of car.

Our suggestion is that the boats which are used for pleasure purposes principally should be shown at the private passenger car show, and that boats which are used for fishing or commercial purposes should be shown with the commercial cars.

We do not, however, advocate holding another show of any kind until after the coming season, as the combined show which has just been held has fully served its purpose.

Yours faithfully,

JAMES & BROWNE, LIMITED.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—When I visited the late mammoth Automobile Exhibition at Olympia I was much disappointed at the way the various makers were all jumbled up, and to find that really high-class firms had only got the same size spaces as some of the mushroom firms with which the industry is blessed—or otherwise. I am afraid I did the proprietors of the Exhibition an injustice as I put down the overcrowding to mere grasping greed on their part, but on asking one of the exhibitors I was told that the real reason the spaces were so small was that room might be found for all the foreign makers and agents for foreign cars. I read in various papers that the English makers have got to the front. If this is a fact, why should they be handicapped by only being allowed a very inadequate space for the display of their manufactures in order that foreigners should be given an equal chance of securing orders? Whilst we are all considering how to grapple with the unemployed question, we overlook the fact that by placing orders for foreign cars the only benefit we

in England get is the small profit the agent makes, and the enormous sums paid for wages and the manufacturers' profits all benefit the foreigner at the expense of our own people. No doubt it is very chivalrous, but is it sound business?

Some little time ago I read of the formation of a Society with a very high-sounding title, something about the British Empire. I have noticed that up to the present they seem to have done nothing beyond getting a free ad. in the motor Press asking for names of makers of copper tubes, &c. If this is a real Society, and not another offspring of that past-master of free advertising, Mr. S. F. Edge, cannot they do something towards holding an Exhibition of *British Manufacturers only*.

With a President and Vice-President and a large portion of the Council of the Manufacturers of Motors Society directly representing foreign firms, it is of course useless to expect them to do anything for the benefit of England, but I do hope that someone will come to the rescue, and acting up to the motto of "England for the English," give us an All-British Motor Exhibition.

Yours truly,

Rosemount, Enfield, Dec. 14th.

CHAS. NEWTON.

THE UNEMPLOYED AND THE ROADS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—Two of the most important social problems of to-day are:—

(1) The improvement of the means of internal communication, and

(2) The provision of remunerative and useful work for the unemployed.

Unfortunately it is the practice to study these problems apart: they are intimately connected and should be considered together.

We have given a considerable amount of time and attention to the investigation of both problems, and desire to make some practical suggestions for the attention of those actively dealing with the employment difficulty and engaged in the administration of public and charitable funds.

It is a fact well known to all economists that the most valuable asset a country can have is a good system of road communication. England has admittedly outgrown the capacity of its existing roads. No new main roads have been made for nearly a century. Our roads are too narrow, the trunk roads being in the main thirty instead of one hundred feet wide. Not only are they narrow, but they abound in dangerous corners and steep gradients. Moreover, they are one day dusty and the next day muddy, instead of being permanently dustless and clean. It is largely due to the insufficiency of roads that the country is confronted with a Traffic Problem, a Housing Problem and a Motor Problem.

It has been proved by experience that the improvement and the construction of roads are the most effective methods of giving work to a large amount of unskilled labour. And this for the following reasons:—(1) One skilled man can superintend a large amount of unskilled labour; (2) The employment is distributed all over the country, so there is no concentration of the unemployed in one particular locality; (3) The local administration of charitable and public funds is rendered possible; and (4) There is no competition with those so employed with existing trades.

The funds that are now being raised, if paid into a Central Fund and properly administered, will provide work for a very large number of persons. For example, assuming that £100,000 is paid into a Central Fund, those engaged in its administration should make it known that the whole or some part of the fund is to be employed in paying for labour employed in road improvements, and that they are prepared to make grants towards those schemes of road improvement which offer the most public advantage, such as the widening of a public thoroughfare, the removal of a dangerous corner, the construction of a dustless road, the reduction of a dangerous gradient, or the building of a bypass road round a village or town for the use of the through traffic. The Central Authority would receive applications for grants from all parts of the country, and it could be made a condition of the grants from the Central Fund that contributions towards the improvements should also be made by the local authority in whose area the road improvement is to be made.

It is on practical lines such as the above that we venture to suggest that the present distress can be removed by affording employment of a character which will result in permanent benefits to the people of this country.

Yours faithfully,

CADOGAN, President of the Roads Improvement Association, Incorporated.

ARTHUR STANLEY, Vice-President of the R.I.A.

W. REES JEFFREYS, Honorary Secretary of the R.I.A.

SIX CYLINDERS v. FOUR CYLINDERS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In your issue of Dec. 9th some very interesting remarks are made with regard to the number of cylinders discussion at present agitating the automobile world. It should be extremely gratifying to all true Britishers that an English invention can so shake the foundation of automobile manufacture, and Mr. Edge can now look back with equanimity to the not very remote time when six cylinders were regarded as a fad. Kidicule and even worse have been their lot, but now the very foundations of the construction of high-grade cars have fallen, and four cylinders are as obsolete as two cylinders became a few years ago. It is extremely amusing to see the people who make or sell 4-cylinder cars getting so fearfully unhappy and excited about it. They really need not worry so. Four cylinders are only obsolete as high grade cars, and will still sell and be sold as useful vehicles for small power for those who cannot afford the initial cost of a 6-cylinder car. I say initial cost advisedly, as undoubtedly power for power the 6-cylinder is lighter in cost of upkeep. I mean in such things as petrol, tyres, and wear and tear generally, so that their occupation is not gone, but only partly so.

All engines are the result of a compromise. If we could make a 30-h.p. engine with only one cylinder that possessed the virtues of silence, smoothness of running, constant torque and flexibility, and still to use the Otto cycle with its all-important scavenging stroke, we should have indeed done something, and six cylinders would be as obsolete as four are now. But we all know that it is impossible to do this and at the same time keep within reasonable limits in regard to the weight, &c. (the fly-wheel would have to weigh about a ton). We can commercially only increase our horsepower to a higher one by adding to the number of cylinders in an engine. The real trouble underlying all this number of cylinders difficulty is the chemistry of the internal combustion motor.

It was definitely settled by Dr. Otto once for all that the waste gases must be thoroughly got rid of, and this and the compression, &c., waste more than three-quarters of an engine's time. Not only do they waste its time, but they exert a retarding effort on the piston. In the first place the exhaust valve has to be opened before the end of the firing stroke is reached, to give the gases a chance to escape so that the useful time is not even a fourth. The piston then loses some of its power in driving them out, next comes the minus pressure of the suction again taking work from the piston uselessly, and finally, and at the very worst part of the cycle, comes the compressing to be done.

Now here lies the basis of the whole matter. We have tried to get away from the Otto cycle, but we cannot at present make a commercial and economical engine on any other principle, and given this, we are given to multiplication of cylinders; the whole history of motor car evolution endorses this. Most of the thinking people knew it from the first, and it was merely a question of time and experiments in manufacture before overlapping of the firing strokes became a necessity. It seems a most illogical position to adopt four cylinders in place of two, and refuse six cylinders, given the difficulties of manufacture are worked out.

The trouble is only partly overcome in 4-cylinder engines, and fusion of the impulses is still far from complete.

Personally, I think an 8-cylinder unnecessary unless the power required is so great that other factors come into play.

The difficulties and drawbacks of the Otto cycle are met when once the impulses are overlapped, which is done in a properly designed six-cylinder, and to add to six is futile unless very high horse-power is required.

One of your correspondents refers to a 4-cylinder car mounting the Cat and Fiddle Hill on its top speed, which appears to have been rather a lowly-geared one. I can quite believe this, I myself have often driven 4-cylinder cars up steep hills on their top speeds if I have been able to get a decent start, and it has been to my immediate interest to do so, but I have been horribly distressed at the pulsations and isolated beats of the engine when she has been just able to do it, and I am far from suggesting that I did my engine, gear, and tyres any good in the process.

The chief point that differentiates the six is that in hill climbing and when crawling along on the top speed even when the engine speed is down to a very low ebb the impulses still overlap, they have no choice in the matter, and the torque, be the speed ever so low, is still a constant one.

Yours faithfully,

South Ealing, Dec. 15th.

L. F. BISHOP.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—In your paper two or three weeks ago a statement appeared that a 6-cylinder car necessitated a greater wheel base than a 40-h.p. 4-cylinder car.

I noticed at the time that a correspondent pointed out that from the published details the 40-h.p. 4-cylinder car had actually 4 inches longer wheel base than the 40-h.p. 6-cylinder, and that therefore if the 6-cylinder design in this direction was bad, the 4-cylinder was infinitely worse.

A reply to this appeared obviously begging the question, as there was no doubt that the 4-cylinder advocate had put himself into an untenable position, but instead of acknowledging himself in the wrong, he merely started to abuse the 6-cylinder principle, evidently thinking it was good policy if he had no case to abuse his opponents.

At the time I was not in a position to know whether your correspondent's statement was accurate or not, but since then I have been able through the French Exhibition to obtain dimensions of the foreign car in which your English correspondent is interested, and I find that the front axle is actually 2 inches further from the

dashboard on the 40-h.p. 4-cylinder than it is on the Napier 6-cylinder, so that not only does the 6-cylinder principle give a better designed motor car, *vide* your correspondent, namely shorter wheel base, but also more room for the body.

I have recently read that some makers are building 6-cylinder cars through panic caused by the success of one firm in this direction. It seems to me that those interested in the foreign cars are also writing letters in moments of panic without due consideration to truth or facts, and in their anxiety to cry down the 6-cylinder actually make a rod for their own backs, as from their own arguments if there is any principle that is wrong on the 6-cylinder, the same arguments applied to the 4-cylinder car makes the latter still further behind the 6-cylinder principle.

Yours truly,
St. Margarets-on-Thames, Dec. 15th. WILFRED DAWSON.

RACES, RECORDS, AND TRIALS.

FRENCH 1906 RACE.—A bad turning in the village of Achères on the Fontainebleau Circuit.

THE TOURIST TROPHY RACE.

MODIFICATIONS IN THE FINAL RULES FOR 1906.

SINCE November 11th, when we published the rules which were then issued provisionally by the A.C.G.B.I., certain modifications have been made, and some further rules have been added, these being as follows:

The new rules are numbered 4 and 18, which have the effect of changing the numbers of those that follow them. They read thus:—

4. Special awards may, at the discretion of the club, be given to those cars competing in the race which are entirely of British manufacture, such cars to comply with the Gordon-Bennett Rules so far as the country of origin is concerned.

18. Efficient mudguards shall be fitted to front and rear wheels, and form portion of body weight.

Rule 6 (formerly 5) has had the word "momentary" added after the word "stop," this being a minor alteration, but in Rule 7 (late 6), which is one over which there has been some considerable discussion recently, the same petrol allowance is now adopted for steam cars as for petrol cars. This rule now reads thus:—

7. The fuel to be used shall be provided by the club, and shall be petroleum spirit having a specific gravity of 0.695 to 0.705 at 60 deg. F. For 1906 the allowance of petroleum spirit for both petrol and steam cars shall be one gallon for every 25 miles, if the

course be in the Isle of Man, and shall be an equivalent amount if the course be elsewhere.

In Rule 10 (late 9), the minimum chassis weight is now 1,275 lbs. instead of 1,300 lbs., and in Rule 11, the total load that must be carried is now 1,125 lbs. as against 1,100 lbs.

In Rule 12 (formerly 11) there are two alterations, for not only is the minimum wheel base fixed at 8 ft., instead of 7 ft. 6 in., but the stipulation is made that oil tanks shall be fixed in the "ordinary standard positions."

In Rule 15 (late 14) the words "half a mile" are inserted after "capable of being driven," and in Rule 17 (late 16) the length of the platform behind the dashboard is specified at 7 ft. 6 in. instead of 7 ft.

Rule 21 (late 19) states that entries will be received (in subsequent years) by the club, 119, Piccadilly, not earlier than the morning after the race.

There are, moreover, a few other slight changes in the phraseology of certain other rules, but these do not materially effect the general conditions of the race.

IN the opinion of the Society of Motor Manufacturers and Traders, as a result of enquiries made throughout the trade, there does not appear to be sufficient demand to justify the Automobile Club in holding their proposed Light Van Trials during 1906.

Speedometer Trials.—The Speedometer Trials of the A.C.G.B.I. will be held in connection with the 4,000 Miles Tyre Trials, in February, 1906. No adjustments will be permitted except in the dépôt, either before or after a day's run. All speedometers must be fitted or provided with a mileage recorder. The entry fee is £25 per instrument, of which amount £15 will be placed to a common fund to be distributed among the tyre entries as a contribution towards the cost of running the cars. Entries will close January 31st, 1906. The following are the points of performance:—The speedometers entered for trial will be observed on the road, and they will be calibrated both before and after the trials. The following points, *inter alia*, will be taken into consideration in making the awards, viz.:—(a) accuracy, (b) durability, (c) the effect of reversing the car on the subsequent accuracy of the instrument, (d) price, (e) rapidity of response to variations of speed, (f) simplicity of construction and attachment, (g) steadiness of reading. The awards will consist of a gold medal to the most meritorious instrument, provided there are three entries, and, provided there are at least six entries, a silver medal to the second best. A certificate of performance will be issued to each competitor.

Gas Lamps.—Classification.

A. Generators (including stored gas containers).—Entrance fee £15.

N.B.—In the case of stored gas the cost shall be that of the complete equipment, including one spare container for each container in use, and excepting only the lamp.

B. Lamps (without generators).—(1) Costing less than £3 retail list price (fee £5); (2) £3 to £6 (fee £10); (3) more than £6 (fee £15).

C. Self-contained lamps.—(1) Costing less than £5 (fee £15); (2) from £5 to £9 (fee £20); (3) more than £9 (fee £25).

In making the awards the following points will be taken into consideration:—

Class A.

(a) Cubic feet of gas generated from one charge at normal rate of supply.

(b) Cubic feet of gas generated from one charge at normal rate of supply per pound weight of generator when fully charged.

(c) Cubic feet of gas generated from one charge at normal rate of supply per cubic foot of bulk of generator measured externally.

(d) Dryness and steadiness of generation.

(e) Ease of cleaning, re-charging, and renewing filters.

(f) Quality of construction.

(g) Time taken daily by entrant in cleaning, re-charging, and in changing filtering and drying materials during period of road test.

(h) Smell and other defects observed during road test, with special reference to continued burning in high wind and when jolted.

(i) Absence of leakage, and power to retain charge.

FRENCH 1906 RACE.—The Fontainebleau Circuit. On the outskirts of Arbonne. The course passes along the road to the left.

Lamp Trials.—The Lamp Trials which are to be held by the A.C.G.B.I., in February, 1906, will be carried out in connection with the 4,000 Miles Tyre Trials. The regulations have now been issued, and they provide that the lamps entered shall be chosen from stock by the club. No cleaning or re-charging will be permitted throughout the trial, except in the dépôt before or after a day's run; but Observers will be permitted to re-light and re-charge as required, after noting the time and cause of any failure. Twenty-five per cent. of the entry fees will be transferred to a common fund, to be distributed among the tyre entrants as a contribution towards the cost of running the cars. The club reserve the right to accept one entry only of each type in any class if the number of cars should prove inadequate. Entries close January 31st, 1906. The classification is as follows:—

(k) Condition of generator after road and other tests.

(l) Cost of gas supplied. [N.B.—This cost will be reckoned on a basis which includes the cost of the generator or equipment.]

Class B.

(a) Candle-power of the central beam of the lamp per cubic foot of gas consumed per hour.

(b) Distribution of light over an angle of 35 deg. in a horizontal plane. [N.B.—The ideal distribution of light will be taken to be that giving a uniform intensity of illumination along the hedges bordering a 20 foot road from a point 10 yards in front of the lamp to the maximum distance of effective illumination.]

(c) Non-tarnishing of reflector.

(d) Freedom from fracture of exposed glass under atmospheric conditions.

(e) Cost of replacing front glass, and its liability to fracture.

(f) Quality of construction and of attachment fittings.

(g) Ease of cleaning reflector, lens, and burners, and of renewing filters (if any).

(h) General appearance and ease of cleaning exterior.

(j) Price.

(k) Condition of lamp after trial.

Class C.

All the points enumerated under Classes A and B will be taken into consideration, with the exception of (c) under Class A.

Oil Lamps.—Classification: (D) Headlights; (E) Side lamps; (F) Tail lamps.

The following points will be taken into consideration in making the awards:—

- (a) Candle-power of the central beam of the lamp.
- (b) Time of burning with one filling of the reservoir.
- (c) Ease of filling, trimming, and lighting.
- (d) Attachment of reservoir to lamp (where reservoir is detachable), with reference to security of attachment and prevention of leakage.
- (e) Device for raising and lowering wick, and means for locking it.
- (f) Non-tarnishing of reflector.
- (g) Quality of construction and attachment fittings.
- (h) General appearance and ease of cleaning.
- (i) Freedom from fracture of glass under atmospheric conditions.
- (k) Absence of defects observed during road test, with special reference to continued burning in a high wind and when jolted.
- (l) Condition of lamp after trial.
- (m) Price.
- (n) Means afforded to driver for ascertaining if the tail lamp be alight in Class F.
- (o) Adaptability, in Class F, to the purpose of illuminating the number plate, without unduly projecting behind it.

Voiturette Record.—On December 14th, a successful attempt on the record of the world for the flying kilometre for voiturettes was made by Barriaux on a Vulpes car. His time was $33\frac{2}{3}$ secs., against the previous record of $36\frac{1}{2}$ secs. The standing kilometre was covered in 47 secs., and the standing mile in 1 min. $10\frac{1}{2}$ secs. (previous record 1 min. $13\frac{2}{3}$ secs.). The timing was by official timekeepers, on the officially-recognised Dourdan Road. This Vulpes voiturette was fitted with "Electric" tyres, Longueuaire carburettor, Eisemann magneto ignition, and a 18-24-h.p. Janus motor.

Gordon-Bennett Cup.—At the International Conference of Automobile Clubs, held in Paris on Monday last, it was decided that no race for the Gordon-Bennett Cup should take place in 1906. At another conference to be held next July, at the time of the big French race, it is to be considered whether the race shall be resumed with modification in 1907. In the meantime the A.C. de France will retain the Trophy.

Italian Events in 1906.—The route of the big Tourist Car Trial, in connection with the Milan Exposition next year, which will be over a distance of 5,000 kiloms., to be run off in ten days, will start from Milan and go south to Naples and Rome, passing through most of the leading cities of the peninsula. Many of the roads selected are of an extremely severe character and calculated to thoroughly test the cars. Already 120,000 francs have been apportioned as prizes, and the trial, is to be under the patronage of the King of Italy.

THE Paris Voiturette Trials, under the auspices of *L'Auto*, for next year are announced to take place during the latter part of April. Some modifications will be introduced into the rules, which are to be issued almost immediately, to enable manufacturers to prepare well in advance for these trials. The unfortunate troubles in connection with malicious strewing of nails in the path of the competing cars, which took place on the last day of the trials which were held recently, have, it is announced, prevented the A.C. of France from officially taking note of the performances of the cars.

MR. CLIFFORD EARP is now in the United States, and is looking forward to repeating his great successes of last year in America with the 6-cylinder Napier car. He will be very prominent at the Fourth Annual International Ormond and Florida Beach Races, where the car is entered for no less than ten events, viz.: The 100 miles international for the Minneapolis Cup, which must be won twice to obtain permanent possession. The race will be run with turns on the beach. One mile international for the Sir Thos. R. Dewar Trophy; the five miles, the ten miles, and the fifteen miles open championships; the one mile, the five miles, and the ten miles heavy weight championships; one mile record trial (heavy weight), and the one kilometre record trial (heavy weight).

**CLUBS AND ASSOCIATIONS.**

Ladies' A.C.—At the last of Mr. R. Sedgwick Currie's technical lessons on the internal combustion engine on December 13th, there were not as many members as usual present. This lesson dealt with the various causes for breakdowns, &c., and Mr. Currie was able to give many practical hints for their remedy. Among other things, he said that if members wished to prolong the life of their tyres they would be careful never to round a corner with the clutch in, as by so doing a very severe strain would be put on the back wheel tyres which would soon result in these being worn flat. When tyres are to be put away for the winter, Mr. Currie advised that they be hung in a cool, dark, and yet dry room. Dark, because rubber invariably hardens, and perishes when kept in the light. A moist or a very warm atmosphere will also cause it to harden quickly.

The L.A.C. Gymkhana will be held in the grounds of the Ranelagh Club on the 30th of June, 1906.

Scottish A.C.—A meeting of the general council of the club was held on the 14th inst., Mr. George Macmillan, chairman of the Eastern Section, presiding in the absence of Mr. Henry M. Napier, chairman.

It was reported that Sir John Macdonald, Lord Justice Clerk, and Mr. R. J. Smith, general secretary, had appeared before the Royal Commission on the Motor Car Acts, and had tendered evidence with special reference to matters affecting the automobile movement in Scotland.

A scheme for the constitution of a department, associated with the club, to comprise the makers and users of heavy and commercial vehicles was outlined and approved.

An application by the Western Section to conduct a Scottish Reliability in 1906, on lines somewhat similar to that conducted by them in May last, was approved.

The decision of the High Court of Justiciary in the case of Bell v. Mitchell was reported. It was considered that this decision emphasised the necessity for obtaining an alteration in the law which bars appeals under motor car cases in Scotland where the fine does not exceed £10.

Arrangements are being made, in conjunction with the A.C.G.B.I., for the conduct of Examinations for Driving and Mechanical Efficiency Certificates being held in Scotland about the end of January next. Detailed information on the subject will be issued shortly. The Examinations, it is expected, will be held in Glasgow and Edinburgh and other centres where the number of applications from the localities warrants. It will facilitate arrangements if, meantime, intimation were made of the names and addresses of probable candidates. Members of the Scottish Automobile Club and other automobilists are requested to bring the matter before the notice of their drivers. Communications on the subject should be addressed to Mr. Robert J. Smith, General Secretary, Scottish Automobile Club, 59, St. Vincent Street, Glasgow.

North Yorkshire Automobile Association.—At a meeting of automobilists held at York last week, it was decided to form an organisation under the above title, to be affiliated to the Motor Union. The draft rules were submitted and approved, the subscription being fixed at one guinea per year. Lord Wenlock was elected president, the Marquis of Ripon, the Marquis of Zetland, and the Earl of Lonsborough were elected vice-presidents; Mr. F. Ware (York), hon. secretary; and Mr. Edwin Gray (York), hon. treasurer.

AERONAUTICS.

The Wright Brothers' Experiments.—What may be regarded as a modified confirmation of the rumours of the Wrights' successes, is recorded by M. Frank Lahm, who, as a member of the Aero Club, has, like everybody else, been greatly interested in the matter. M. Lahm has correspondents in America, and on hearing vague rumours about the Wright experiments, he wrote on the 25th of November to one of these, M. Bierce, to ask him if he could find out anything on the subject. M. Bierce replied that all he knew was that two young men of the name of Wright had been carrying on experiments of the kind referred to for some time, which had been alluded to, to a certain extent, in the papers, but that these experiments had taken place at a distance from Dayton in a very retired spot. This, of course, might refer perfectly well to the prior experiments of the Wrights with which all the world is acquainted. But a more direct confirmation comes from another source. On the 1st of December, the same M. Lahm telegraphed to a Mr. Weaver, of Dayton, and received from him the following reply:—"Dayton (Ohio), 3 Décembre 1905. *Prétentions complètement vérifiées . . .*"

As we understand that M. Lahm explained in his cablegram to Mr. Weaver what the assertions in regard to the Wrights' exploits were, his cablegram in reply would certainly appear to afford a certain modified amount of confirmation.

In support of this view, it must be remembered that the Wrights have never been men to rush into publicity prematurely. No one knew anything about their first classical series of gliding experiments until they communicated them to the Western Society of Engineers, and even Mr. Chanute, who was acquainted with them, kept silence about them. It must also be remembered that they have never hitherto pretended to accomplish more than they have actually effected. In the autumn of 1903—the date of the last personal communication the world has had from them—they accomplished free flight with a motor-driven aeroplane (of upwards of eighty yards through the air, which occupied exactly half a minute), and they then packed up their apparatus and went home, saying to one another that they were convinced that the age of the motor-driven aeroplane had come. Since then the world has had from them—absolute silence. Is it to be believed that enthusiastic experimenters who have accomplished what we know them to have accomplished—free gliding flight on an extended scale, and the first free flight *from the ground*, of a motor-driven aeroplane carrying an aeronaut, which the world has ever seen—have been doing absolutely nothing since the autumn of 1903? The supposition is opposed to all we know of human nature. Men who have done what they have done have most certainly accomplished more, even if they have been killed in the attempt, or have committed suicide in consequence of failure. But they are still alive. In fact, everybody interested in aeronautics has been waiting to see what they would do, and nearly everybody has been certain they would do something great. One corner of the curtain having now been raised, we think the Wright Brothers should make an authoritative pronouncement to one of the technical papers, either on that or this side of the Atlantic, which would make a clean breast of the whole business, and set anxiety at rest. Let us trust that some such revelation will soon be vouchsafed.

ANOTHER confirmation, for what it is worth, of what we may at present be excused for entitling the "Wright legend," has been further provided by *L'Auto*. Our contemporary has a collaborator and correspondent in New York, of the name of Robert Coquelle, and since the Wright legend has been generally promulgated the paper instructed M. Coquelle to proceed to Dayton and ascertain, if possible, what truth there was in the various rumours. This M. Coquelle accordingly did, and despatched to his paper the following telegram (published in *L'Auto* of the 14th), dated from Dayton: "The Wrights have refused to show me their apparatus, but I have succeeded in seeing and questioning a number of credible witnesses. It is impossible to doubt the success of the experiments announced." Our contemporary will, of course, ultimately receive, and doubtless publish, letters with details. So far, therefore, it will be observed that we have now a third confirmation, as far as it goes and for what it is worth, of the statements that have already appeared. The situation is distinctly silly, particularly as it seems more and more impossible to deny that there must be at least a basis of truth in the statements promulgated. In the name of all aeronauts, at present tortured by curiosity, we would once again invoke the Wright brothers to issue an authoritative statement of what they really have accomplished or not accomplished! Even if they have only failure to chronicle, no one will think any the worse of them. They have done too much to be ashamed to acknowledge a defeat!

APROPOS of the alleged sensational performances by the Wright brothers, several papers have published so-called illustrations of their apparatus. These are invariably reproductions of the original gliding machine with which the great glides in 1902 were effected, and which we reproduced fully about the time of those successful exploits. It cannot be too generally borne in mind by the public interested in the subject, that this is *not* the machine with which the first free motor-propelled flight of November, 1903, was effected.

OUR French contemporary, *Le Genie Civil*, contains in its issue of December 9th an excellent illustrated article dealing with the recent performances of the Lebaudy airship, giving the itinerary of the tours from the town of its birth to the camp at Chalons. The present structure of the great airship is also illustrated by careful line drawings, and the shed constructed to accommodate it at Toul, half of which is formed by a deep excavation in the ground, is also shown. The various exploits which were chronicled at the time they were carried out, in THE AUTOMOTOR JOURNAL, are described, and the article in question forms an important and succinct *résumé* of last year's performances of the Lebaudy airship.

MOTOR CYCLING.

THE first quarterly trial of the Auto-Cycle Club is announced to take place on January 20th.

FOR the International Cup Race for motor cycles, June 29th has been selected for next year. The race will take place in Austria, the country at present holding the trophy.

M. RIVIERRE completed at Paris on the 14th inst., on a Mototri Contal, 6,500 kiloms. in seventeen days—a severe test embracing every variety of road, hilly and flat, throughout France. He reports that he has used the same set of tyres during the entire run.

A RICHARD-BRASIER CHALLENGE CUP.—On Saturday last, at Leicester, there was quite a large gathering of privately owned Richard-Brasier cars, when the well-known British agents—Messrs. Mann and Overton—awarded a 30-guinea silver challenge cup to the owner of the best turned out car. At a dinner given by the firm on the previous evening, to which we travelled down luxuriously from London on one of the new 40-50-h.p. models, the intention was announced of making an annual event of this very pleasant function, and of thus taking advantage of a very practical method of encouraging owners and drivers to interest themselves in the condition of their cars. On this occasion, the cup was awarded by the judges—amongst whom was Mr. Alan McAlpin, the Hon. Sec. of the Leicestershire Club—to Mrs. S. H. Akroyd of Waverton, Woburn Sands, for her 16-20-h.p. vehicle, which is seen on the extreme right; the driver was presented with the £5 note, which also forms a part of the scheme.

Clear the Way!—We quite recently drew attention to the present day inadequacy of the "Hi! hi!" with which the firemen of the Metropolis attempt to clear the way before them in our crowded streets, particularly when associated with motor cars conveying Brigade officers. When general noise was less, the method was perhaps effective, but it has long ceased to be so, and we pointed out that something in the way of a gong or bell would be more effective. We are interested, therefore, to find that this innovation has been adopted by the Metropolitan Fire Brigade, the chief officer of which has recommended the purchase of 150 large bells.

THE development of the motor 'bus is leading to a regular rush to appropriate names—following the lead of the "Pioneer," "Vanguard," and "Arrow" lines—that are likely to be considered popular, of the kind which recall the old knife-board omnibus days, when we had Westminster "Monsters," Britannia "Marvels," and Islington "Favourites" (of which, by the way, the latter still survive) flaunting their weird devices in all directions. The method adopted is usually to register a company with £100 nominal capital and assume the names desired, and amongst names so "earmarked" for future exploitation we notice "Mercury," "Rocket," "Dart," and "Express."

SOME time ago, we alluded to the shocking condition of the stretch of road treated with tar at Byfleet. In the neighbourhood of Cobham, another stretch of road has been similarly treated, and appears at present to be even worse than the Byfleet stretch, and exceptionally slippery. At any rate, attention was called to the matter by Mr. W. Christmas, at a recent meeting of the Surbiton Urban District Council, and it was pointed out that a number of motor car accidents had occurred on the stretch of road treated for dust prevention owing to this cause. Instructions have been issued to the surveyor to erect notice-boards pointing out that the stretch of road in question is dangerous for motor cars. Will they be called Christmas greetings?

Petrol Motor Railway Coaches.—The London, Brighton and South Coast Railway are about to introduce petrol motor coaches on their branch line between Brighton and Kemp Town. They will be capable of holding forty-eight passengers and will make twenty-nine journeys each way every week-day and twenty-six on Sundays. A platform has been erected between Kemp Town and Lewes Road, to be known as Hartington Road halt, where all cars will call to take up and set down passengers. This service will, of course, replace that now in existence.

THE marriage between Mr. Alexander Winton, the President of the Winton Motor Carriage Company, of Cleveland, Ohio, U.S.A., and Miss La Belle McGlashan, of Paisley, was duly solemnised on December 12th at Glasgow. Mr. Winton was born in Scotland, and spent part of his boyhood in the second city of the British Empire.

ON Saturday last, Mr. Henry J. Lawson was released from Wormwood Scrubbs Prison after having served the sentence of twelve months' imprisonment which was passed upon him about this time last year, when in conjunction with Mr. Ernest T. Hooley, he was indicted at the Central Criminal Court with having obtained money by false pretences from Mr. A. J. Payne. Mr. Hooley, it will be remembered, was acquitted. Mr. Lawson, who was looking well when he emerged from his confinement, was met by his son and two friends on a motor car. Mr. Lawson, we understand, has during his incarceration been confined mainly to the infirmary, and, needless to say, his active brain has not been idle during his unfortunate experience. It is stated that he has perfected two inventions in connection with the motor industry, both of which he proposes as early as possible to place upon the market. In addition, a book is to be issued by him early in the New Year on his experiences of prison life, facts which point to there being no loss of energy in Mr. Lawson by reason of his enforced absence.

"IT is about time we heard of the West-End heiress who has married a motor-'bus conductor."—*Financial News*.

QUITE a considerable number of members of the new Government are either automobilists or favourably disposed towards the movement. Amongst car owners may be reckoned the Marquis of Ripon, Lord Aberdeen, the Earl of Crewe, Lord Tweedmouth, Earl Carrington, Sir Edward Grey, Sir Robert Reid, Mr. Asquith, Mr. Herbert Gladstone, and Mr. L. V. Harcourt. Among the members of the Ministry favourable to the movement, though not actually automobilists themselves, may be reckoned the Earl of Elgin, Mr. Haldane, Mr. Lloyd George, and Mr. Sydney Buxton.

THE London County Council has agreed to adopt the proposed scheme for establishing ambulance services to deal with street accidents suggested by the General Purposes Committee. This scheme involves providing two ambulance stations, motor ambulances, and wheeled litters, and a system of giving calls by means of street call-posts fitted with telephones. The provisional estimate of the expenditure which would be involved in this beneficent scheme is £5,200. One of the proposed stations is to be at Bridge Wharf, Lambeth, and another near Charing Cross.

A REPORT of accidents made in New York by Laffan's Agency points out that all sports exact their tale of accidents: football during the year 1905 claiming 21 victims, base ball 12, horse racing 9, pugilism 6, horsemanship 4, and gymnastics 2. It is noteworthy that the number of accidents attributed to the automobile have not been regarded as worth recording.

MOST people would think that motor car goggles and masks were such unbecoming disguises that no one would willingly assume them unless compelled by the exigences of the road. That an elaborate *Bal masqué* should be arranged in which the guests are to disguise themselves in motor goggles till midnight, certainly strikes one as belonging to the category of those tasteless peculiarities so characteristic of the modern world.

A POLICE case, somewhat similar to the Leeds case which we mention elsewhere, though not involving a charge of perjury, was that of Charles Poulett, who was fined £2 and costs at Whitchurch, Shropshire, for being found, in a perfectly contented state, at midnight, a mile outside Whitchurch in an intoxicated condition asleep in his car, which was partially overturned and fast in a bank. It took two hours to extricate the car from its difficulties.

Last week we give a few particulars of the very successful Fancy Dress Ball which took place in Coventry Assembly Rooms amongst employees of Messrs. Humber, Limited. The function was a huge success, there being nearly 300 dancers and about 800 spectators. The success was the more creditable from the fact that the whole of the arrangements were in the hands of the Humber employees at the Coventry Works. We are able to give above a flashlight photograph of the scene in the ballroom, when the dancers were specially grouped for the purpose of the picture. A special feature was the giving of prizes for the best lady's and gentleman's fancy dress.

the various features of his triumphant experiences, which, of course, mean the many triumphs of the Michelin tyres.

AT his recent visit to the Midlands His Majesty King Edward joined the shooting party at the Clowne Hills, near Welbeck Abbey, in his motor car. The Royal car took up a position in the direction in which the game was being driven, and the King shot from the seat of his car without having to take the trouble to disembark, and, we understand, enjoyed very excellent sport.

A SENSIBLE correspondent of the daily Press points out the great importance of teaching children in elementary schools the ordinary rules of the road and the necessity of keeping out of the way of fast moving traffic. The matter has been put before the Secretary of State, and the letter written by the correspondent to whom we refer has been laid before the Board, but so far nothing has been done.

THE PARIS SALON.—A Panhard Touring Car, which has the driver's seat entirely enclosed both in front and at the side. This is one of the few novelties in carriage construction at the Salon.

KAISER WILHELM has favoured the Fiat Company with an order for a 70-h.p. car, this being the third of the same make which the Emperor has indulged in.

THE neighbourhood of Chertsey has earned for itself an unenviable reputation. It appears that the motorists passing through the neighbourhood are specially liable to be greeted with salvos of stones from the small boys which abound on the Chertsey Road. One of them was recently brought before the police court and fined 10s. for this very objectionable method of amusing himself.

FOR a long time Mr. Edison has stoutly maintained that the car of the future was going to be electric, provided, of course, with his special form of battery. He would never give in, in words, upon the subject. Now, however, it is reported that he has recently taken delivery of a 1906 Grout 4-cylinder touring petrol car. Facts speak louder than words, and we may conclude that even the inventor himself does not now think that the Edison-battery-propelled electromobile is destined to run everything off the roads of the Great Republic of the West.

EVERYONE familiar with the advertisement hoardings on the Continent and some of our principal towns knows the comic figure of "Bibendum," a personality constructed entirely of motor-car pneumatic tyres, which has become almost as amusing a personality as "Sunny Jim" was some time ago. "Bibendum" has become a sort of trade mark to the Michelin Tyre Company, and they have, with the Christmas season, published an amusing skit, illustrated in colours, of his origin, and of

SIR T. BROOKE HITCHING, who is convinced that the tramways of the London County Council do not pay, uttered a solemn warning last week, in reference to the proposed further prodigal expenditure on tramways of the Council, pointing out that the Council had made no allowance for the effects of motor 'bus competition on tramway receipts. Every £100,000 spent on tramways will result, according to Sir T. Brooke Hitching, in a proportion of loss. Lord Welby also warned the Council that they were overstraining their credit.

WE are requested by the solicitors for Mr. W. Clifford Earp, the well-known racing-car driver, to state that their client has never had any connection with the "Bettoruss" Non-Skid Tyres, Limited, and that the circular and testimonial recently disseminated in connection with this tyre, mentioning a Mr. Earp, do not in consequence in any way refer to him.

A new type of "Station Car," of which we give a photograph, has recently been placed on the market by the Wolseley Motor Car Company, to meet the demand for a vehicle equally suitable for the carriage of luggage from country houses and for reaching shooting lodges at a distance. It is particularly adaptable for the latter purpose when a number of guns and dogs have to travel a long way. For this purpose the car body has been built extra wide and low. A 12-h.p. motor is fitted, and even the steepest hill can be easily surmounted with full load.

COMPANY DOINGS.

In the report of the British Electric Traction Company, it is announced by the directors that satisfactory progress has been made by the British Automobile Development Company, in connection with which works have been erected at Loughborough for the manufacture of motor omnibuses and heavy haulage vehicles. They anticipate a large demand for British-made vehicles of this description, and they believe that the Automobile Company will be in a favourable position to meet it.

At the Dunlop Pneumatic Tyre Company's Annual General Meeting, held last week under the Chairmanship of Mr. Harvey du Cros, the Chairman, in dealing with the motor-tyre side of the Company's business, announced that they had not been disappointed in looking for large and satisfactory results. They were now making a splendid tyre and were quite unable to meet the demand, but they hoped to overcome this difficulty when their mill was completed. He referred with justifiable pride to the action of their company in connection with motor tyres in the Vanderbilt Race in America. At a moment's notice they had shipped tyres to America, from one of the Dunlop Company's works in Europe, to take part in the Vanderbilt Race, and their efforts had met with unexampled success, from the fact that the tyres with which they supplied the winning car went through the race without any difficulty whatever. This was accomplished in the face of the many difficulties which racing provided in the severe strains put upon tyres, as the cars skidded round the corners instead of being driven round. The Chairman further referred to the large development which is taking place in connection with solid tyres for motor omnibuses, and he was glad to say that the company was in a strong position to fulfil any demand in this direction made upon it.

The Star Cycle Company, Limited.—Following the passing of the dividend on the ordinary capital for seven years, and with preference interest four years in arrear, the shareholders of this Company, in spite of the directors not recommending the payment of any dividend for the past year, have reason to be pleased with the decided improvement in the outlook of the Company's affairs, which is set out in the report for the year ending September 30th last. The report states that the trading profits for the year amount to £7,370 and the net profits £4,123, making, with the balance brought forward from last year, £1,335, a total to the credit of profit and loss of £5,458. Profits from the cycle section have not been good, but the directors anticipate a very satisfactory result for

1906. Business in the motor section is highly satisfactory from every point of view, and the directors are confident of even better results therefrom in the immediate future. It is proposed to place to reserve account £1,000 (bringing that fund up to £10,000), and after paying directors' fees to carry forward the balance of £4,058.

Singer and Co., Limited.—Mr. George Singer presided at the annual meeting of shareholders of this company at Coventry on Monday last. The accounts showed a net profit of £8,796. After providing for the debenture interest, there remained £796 in reduction of last year's deficiency, leaving it at £4,960. The chairman said that the profit on the cycle department had been absorbed in the outlay upon the preparations for the manufacture of motor cars. As to the coming season, there would be only very slight alterations in the standard pattern, but it had been decided to make motors up to 28-h.p., having four or six cylinders of the vertical type, and special attention would be given to the production of a car for commercial purposes.

NEW COMPANIES REGISTERED.

Automobilia (Limited), 532, Oxford Street, W.—Capital, £20,000 in £1 shares.

J. Brittain Pash (Limited), Market Road, Chelmsford.—Capital, £14,000 in £1 shares (7,000 six per cent. preference). Object, to acquire the business of agricultural engineers, cycle and motor manufacturers, carried on by J. B. Pash at Chelmsford, Colchester, Braintree, Bishop's Stortford, Romford, and Saffron Walden, and also shares in the Briton Cycle Company, Limited. First directors: J. B. Pash and D. J. Pash.

Express Motor 'Bus Company (Limited).—Capital, £100 in £1 shares.

Mann and Overton (Ireland) (Limited), 7AB, Lower Belgrave Street, S.W.—Capital, £2,100 in £1 shares. Object, to acquire the exclusive agency for Ireland of all motor cars and spare parts which Mann and Overton, Limited, sell there. First directors, J. J. Mann, J. T. Overton, and E. M. Stirling.

Pearson and Pearson (Limited), 52, Elm Grove, Southsea.—Capital, £2,000 in £1 shares. Object, to carry on the business of manufacturers of motors, motor cars, &c.

Pedlar Brake and Two-Speed Gear Company (Limited), 160, Temple Chambers, E.C.—Capital, £100,000 in £1 shares. First Directors, C. E. Hare, H. A. Johnston, G. M. De Vere Beauclerk, M. Pedersen, H. S. Close, J.P., and A. G. G. Hervey, J.P. General manager, W. G. James (Crypto Car and Cycle Company).

The number of commercial travellers' motor carriages which are now seen in regular service in London and the provinces is remarkable, it being found by experience that vehicles of this nature completely pay for themselves, by the extra advantages with which they provide travellers, in an incredibly short space of time. Messrs. Argylls London, Limited, have sent us a photograph, seen above, of one of their new type of vehicles of this class which they have recently supplied to Messrs. Asprey and Co., of Bond Street. The inside of this van is fitted with shelves, with two upholstered seats in the rear portion, access being gained also from the rear. Otherwise the van is throughout one of the Argyll standard 10-12-h.p. vehicles. With its normal load this vehicle has been tested up Fitzjohn's Avenue on its second speed, which it takes quite readily.

COMMERCIAL POINTS.

WE recently mentioned that a company was being formed in Italy for the manufacture of Napier cars and marine motors. This has now been arranged under the title of San Giorgio, Societa Anonima Italiana. The Duke Leopold Torliona is President of the Board of Administration, and Chev. Attilio Odero is the Vice-President. Chev. Pietro Micheli is the Managing Director, and other Directors are Duke Visconti di Madrone, Count E. Nicolis of Robelant and Marquis Franco Carrego, Prince of Lucedio, whilst other notabilities appear amongst the founders and the rest of the Directors. Until the new Company's factory is in running order, an order for a considerable number of British-built Napier cars has been placed, and altogether the powerful combination which has been formed for exploiting cars on British lines in Italy, is a very flattering testimonial to the splendid position which has now been attained by British-designed cars.

THE "Deasy" car is the name of a new 4-cylinder 16-h.p. British-made car, for the manufacture of which an up-to-date factory will shortly be erected at Coventry under the guidance of Capt. Deasy. Capt. Deasy will have associated with him as designer and works manager, Mr. E. W. Lewis, who has in the past been known prominently, firstly in connection with the Daimler Company, and latterly with the Rover Company. Mr. A. C. Hills will be in charge of the commercial side of the business.

At the Birmingham Motor Car Show to be held at Bingley Hall, January 19th to 27th, space has, we learn, been secured for exhibiting some fine examples of British and foreign cars and commercial motor vehicles. The exhibition has received excellent support from

the trade. Invitations, accompanied by free tickets, will be sent by post to every motor car and motor cycle agent within a 60-mile radius of Birmingham, and in addition to all professional and business men and likely buyers of a motor car in the Midlands.

By special permission the band of H.M. 1st Life Guards has been engaged, and will perform daily.

Enquiries in regard to the exhibition should be addressed to Geo. W. Owen, Secretary, Exhibition Offices, 57 and 58, New Street, Birmingham.

At the Paris Salon no less than 896 wheels are fitted, we learn, with Continental tyres.

MR. E. H. LANCASTER, managing director of the Clement Motor Company, Limited, had a letter addressed to him at 3, Lancaster Street, Lancaster Square, W.C. It found him. His address, as is generally known, is 3, Leicester Street, Leicester Square. There is much in Shakespeare's query, "What's in a name?"

MESSRS. CHARLES JARROTT AND LETTS, LIMITED, have appointed Messrs. John Croall and Sons, Limited, of 126, George Street, Edinburgh, sole selling agents for De Dietrich cars in Scotland.

THE Duke of Portland and the Countess of Warwick we hear have selected 40-h.p. De Dietrich cars for their use during the coming year.

H.M. THE KING OF SPAIN has just placed an order for a 24-40-h.p. Fiat car.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.I.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application; the second, at the end, the date of the advertisement of the acceptance of the complete specification.

22356. 17th October, 1904. Improved Automobile. Robert Goldschmidt, 54, Avenue des Arts, Brussels. Date under International Convention, 17th October, 1903. The object of this invention is to effect the direct transmission between the shaft of

current by making contact with the metal sector, *g*. The point, *q*, of this sector being insulated, it follows that if the handle, *i*, be brought to *q* the ignition circuit will be broken. The control of the motion forwards and backwards of the motor by the driver

the motor, which is one of four cylinders, and the shaft which controls the differential gear or the driving shaft, while at the same time it admits of backward motion by the use of a special arrangement for the distribution and ignition, rendering the motor reversible. There are three figures. Fig. 1 is a plan of the arrangement. In the four-cylinder explosion motor, *a*, the distribution is controlled by a shaft, *b*, having double cams with inverse projections and an intermediate neutral part which admits of reversing the direction of travel through a clutch, *c*, with friction plates. The clutch is controlled by the pedal, *d*, for the purpose of coupling directly the shaft, *e*, of the motor to the shaft, *f*, actuating the differential gear. A longitudinal displacement of the distributing shaft, *b*, towards the front or the rear can be obtained by a tubular rod located in the steering-wheel tube, *g*, and rotatable therein. At its upper end, above the wheel, *h*, the rod has the little handle, *i*. At its lower end, beneath the box, *j*, the rod bears a cone wheel, *m*, gearing with the cone wheel, *n*, of the transverse shaft, *p*. A fork, *r*, on the other end of this shaft engages the cam shaft, *b*, moving it to and fro under the control of the handle, *i*. The ignition ring, *q*, of well-known type, and having four internal contacts, is mounted concentrically to the shaft, *b*, towards the end thereof, which end bears two keys or cams for the distribution of the ignition, one for the forward and the other for the backward motion. These keys are respectively brought into the track of the contacts by shifting the shaft, *b*. The stop, *j*, which forms part of the handle, *i*, closes the circuit of the ignition

is effected as follows:—For the first start the motor is started by hand in the usual manner, the handle, *i*, being pushed down towards the right, thus giving a full admission for the forward motion. In order to reduce the speed, the handle, *i*, is moved towards the neutral point, *q*. In order to stop the motor in such a position that it can restart by itself at the contact the handle, *i*, is pushed downwards to the bottom in the direction of the full admission, the brake is taken off, the handle, *i*, is brought to the point, *q*, which cuts off automatically the current by means of the interrupter, *j*, and the handle, *i*, is then brought rapidly to the point, *q*. All the valves then remaining closed, the four cylinders are filled with explosion gas. When it is desired to again start the motor for the forward motion the handle, *i*, is pushed down to the left, the handle, *i*, is also pushed towards the left and the motor will start in the backward direction, because ignition will take place in one of the cylinders. The control is thus effected by moving longitudinally the half-speed shaft with its cams and ignition gear.—November 29th, 1905.

PASSING EVENTS.

1905.

THE year which has just come to an end will be regarded in many respects as memorable, and in nearly all respects as satisfactory, in the history of the automobile movement. There have been few sensational developments, but progress has been very marked in every direction, and an all-round improvement has resulted. It is not generalising too much to say that the attitude of the public towards the automobile has undergone a distinct change. If there is not less hostility in certain circles, there is at least an increasing tolerance towards the new locomotion on the part of the great bulk of the public. Even in remote agricultural districts where prejudice lingers longest, decidedly fewer diatribes against the automobile are to be heard, and even when still delivered by the local quidnuncs and oracles of the village bar and village green, are less frequent and less virulent than they used to be. In short, a kind of subtle change can be recognised. It is the same sort of change that came over the country many years ago when the bicycle, after being long regarded as an objectionable innovation, began to be recognised as a permanent institution. This is perhaps one of the less tangible, but not the least important phenomena of the past year, and is full of promise for the future.

Of course, no single cause has conducted to this almost impalpable, but noticeable, alteration in public opinion, but among those which have assisted in bringing it about we think we should be right in specifying the increased demonstration of the utility of the automobile. This has been specially brought into prominence during the last year by those who had previously employed cars almost solely as a plaything, now adopting them for *bonâ fide* travel. There is all the difference in the effect produced on popular opinion by the possession by some local magnate of a machine on which he merely rushes out several times a week for a run round the country, and a vehicle which he employs to perform regular journeys either between his home and his business in town or between one part of the country and another. The pre-eminent utility of the car has thus been demonstrated more frequently than ever before, and there has been a corresponding increase in popular respect for it. One cannot help thinking, too, that the very unfair and un-English tactics adopted by the police in their dealings with motorists, which have provided many a smile (and some stronger expressions of feeling), for our readers, have assisted, as all unfairness ultimately does assist, in bringing about a reaction in favour of automobilism. Another development that has unquestionably contributed to affect the popular mind in a similar manner has been the almost phenomenal success, particularly in the Metropolis (though not by any means confined to the Metropolis alone), of the motor 'bus. Formerly, no doubt, amongst the people at large there may, perhaps, have been a tendency to associate the new locomotion with the convenience of the rich, and to regard it merely as having provided a new amusement for the moneyed classes. But the motor 'bus has brought home to the man in the street that automobilism is going to benefit him too.

When we turn to the consideration of the development which the past year has seen from the engineering point of view, we find similar cause for general congratulation. There has been little of a startling or revolutionary character in car design. But there has been an

enormous amount of work done (mostly concentrated on the further perfection of types which are becoming more and more standardised) which does not necessarily appear above the surface. We refer particularly to such subjects as the adaptation of the dimensions and strength of parts scientifically and mathematically to the precise requirements that they have to fulfil, with the consequence that those parts which require to be strong and massive have been made so, while those on which economy of material and diminution of weight can, without disadvantage be effected, have been lightened. The result has been vastly to increase reliability, and the occasions on which a car can be observed, for anything but a tyre trouble (and even those are not very frequent now) broken down on the roadside, have become very few and far between. This excellent effect has been due, no doubt, not only to the more careful calculation and utilisation of experience to which we refer, but must also unquestionably be very largely ascribed to greater care in the selection of materials, to the utilisation of high-class steels of the nickel and tungsten order (to which attention has been given from time to time in this journal), as also to the gradual elimination of the small maker who used merely to assemble engines, gear boxes and other parts made by various manufacturers into a complete car, as well as to the general tendency towards standardisation and manufacture on a large scale which has resulted from many of the leading firms in this country becoming capitalised and organised on an increased and adequate scale.

Corresponding to the tendency which we have mentioned—the more utilitarian employment of even the pleasure car—it is to be noted that the past year has seen a general movement towards the development of even higher-powered cars than last year, but designed, be it noted, not so much for greater speeds than formerly, as for efficient hill-climbing under all circumstances and for the satisfactory transport of the extra weight represented by comfortable and luxurious bodies suitable for lengthy travel. There has, however, also been a marked tendency towards the development of that very useful type of comparatively light car that has been especially encouraged by the Tourist Trophy regulations, the thoroughly well-designed machine with an engine of from 12-h.p. to 20-h.p. and seating capacity for 4 or 5 persons. Small and cheap cars of the run-about order are still comparatively few in number, and very little has been done during the year—relatively speaking—in the direction of further development. Those makers who build really good models must, however, have again reaped an excellent harvest.

Dealing with details and accessories, one may note the decided development of magneto ignition, particularly of the high-tension type. Carburettors have in general undergone but little or none of that change which was so characteristic of 1904, but there has been a tendency, wisely enough, to make brakes more powerful, to employ various types of metal-to-metal clutches in place of the leather-faced variety, and towards the adoption of improved systems of lubrication, involving principles of forced feed and automatic circulation.

Thus from the engineering and commercial points of view the year 1905 has been pre-eminently a practical one. It is not without significance, therefore, that the same year has witnessed the last (to all appearance) of the Gordon-Bennett Race. Though various attempts have

and are being made, particularly in France and America, to regalanise high-speed racing into life, there has unquestionably been a general tacit consensus of opinion that all that high-speed racing is likely to be able to teach us has already been learned, and that mere professional racing is quite useless. The result has been the elaboration of a more practical type of race which combines something of the requirements of a reliability trial—of increased stringency—with the excitement and attractive features of a race. We refer, of course, to the Tourist Trophy Race. The year 1905 will probably always remain memorable as the year of the first Tourist Trophy Race, an event which, held, as every first event must be, under more or less imperfect rules, has demonstrated that it is still possible to employ the racing principle in such a way as to be of real commercial utility. This is no small triumph to those who have organised it, for the days when lengthy reliability trials of the type which once was so useful have, for the reasons we have pointed out above, now passed away.

As regards marine motoring, the year has been to some extent a disappointment, for as yet the sport does not appear to have met with enthusiastic reception from the public. The development of the motor boat has not been altogether as rapid as might have been anticipated, though solid and substantial progress has been made in the adaptation of motor propulsion to boats of various characters. *En revanche*, as the French say, aerial navigation, as we point out elsewhere, has undergone some sensational developments, in which department we have chronicled not only the splendid performances of the Lebaudy airship, but the apparently definitive solution of free flight by mechanically-propelled aeroplanes, which there now seems no reason to doubt has been accomplished in America.

By keeping in touch with and providing a faithful chronicle and carefully considered commentary on the progress of the year, THE AUTOMOTOR JOURNAL has but continued its established policy, and it has been successful in appealing to a much wider circle of readers than ever before. In fact, the increase in its prosperity and the general recognition that it has received have been more marked this year, as compared with the relative increase in former years, than previously, which is satisfactory evidence, if any were required, that our efforts to represent not merely the social and amusing side of automobilism, but its more serious aspects, have met with substantial appreciation.

A Mistaken Project.

THE pertinacity of the gentlemen who have determined to "push" a road from London to Brighton specially confined to motor traffic is remarkable and would be admirable—in a better cause. They have prepared a Bill, and are going to bring it in in the next session of Parliament, their measure having already issued from the Private Bill Office of the House of Commons. It is styled the London and Brighton Motor Way Bill, and if it ever passes into law will enable a company to be formed and empower it to complete a special road, lighted by electricity, from London to Brighton, which will be restricted entirely to motor traffic, and electricity will be supplied for propelling any vehicles which may wish to adopt that means of locomotion. The promoters of the Bill are comprehensive in their ideas. Their motor road (if any) is to commence at Croydon and terminate at Patcham,

a few miles on the London side of Brighton. They are to raise two millions and a quarter of capital in £10 shares. They are to build a special road 40 miles, 1 furlong and 1 chain (that one chain is good) in length, and they are to take five years building it, and to keep all horse drawn traffic off it when it is built. Well, we have always been against projects of this kind, and our reasons have been the very obvious ones that the moment the principle is admitted by the legislature that motor vehicles should have roads to themselves, tremendous force will be given to the contention of the anti-motorists that they should not be allowed on ordinary roads, or, if allowed at all, only permitted to attain a prohibitively slow snail's pace. It might be very nice to have a road from London to Brighton restricted solely to motor traffic, on which a few speedomaniacs could tear along at sixty miles an hour, though how the company who builds the road will get their money back is quite a different consideration, but we think that enjoyment would be very dearly purchased by any strengthening of the opinion amongst the people in this country generally that motor cars are to be confined to special roads. That this would be the ultimate result we do not for a moment doubt. The Members of the House of Commons, therefore, who have the real interests of the automobile movement at heart, will, we think, be justified, when the measure is introduced, in uttering the simple but sometimes fatal words, "I object."

The Parliamentary Campaign.

THERE is scarcely a more important consideration for all interested in the future prosperity of the movement than the tactics to be employed by automobile associations such as the A.C.G.B.I. and the Motor Union (and by individual automobilists as well) in regard to the approaching General Election, which, it is now pretty certain, we may look forward to at the commencement of the new year. We referred, the week before last, to the very admirable suggestions put forward by Lord Harmsworth as conditions to which candidates for Parliamentary election should be required to subscribe before car owners should agree to placing cars at their disposal for electioneering purposes, and last week we announced with satisfaction that the Motor Union had agreed to adopt the same lines and require candidates to subscribe to practically the same "articles of faith"—and performance, before undertaking to assist them. So far all is well. The principle for which we have always battled, that the support of automobilists was of the highest importance in determining the result of Parliamentary elections, has been recognised, and what is even more important still, it has been recognised by the most representative automobilist bodies in the United Kingdom that the automobilist cause is to have precedence of everything else. At the same time some scheme of organisation is necessary. There may be many objections—some possibly of a legal character—to a body like the Motor Union taking part as such in lending vehicles for Parliamentary candidates. After all, the Union will, in the main, have to rely for support, that is to say, for the vehicles which it can place at the disposal of any candidate, mainly on the local automobilists in the districts in which the election is taking place. This is particularly so in a General Election, as a concentration of forces on particular constituencies will hardly then be possible except in the case of

those elections which, by the idiosyncracies of British law, take place considerably after the others. Of course, where two candidates are both supporters of the automobile movement, and both subscribe to the articles of faith referred to, the Motor Union will naturally refrain from taking up an attitude more in favour of one than the other. In that case, it will no doubt wisely leave the local automobilists to support with their influence and their cars the candidate to whom their political or other sympathies incline them. Much the same will be the case in those unhappy constituencies in which both candidates are equally opposed to the movement, though there, of course, the local automobilists will in most cases be well advised to leave both of them severely alone and let them obtain their help elsewhere. The important cases, and those in which the Motor Union can make its influence, organisation, and the energy of its secretary specially and powerfully felt, will be the cases in which one of the candidates is a supporter of the movement and signs the articles, and the other refuses to do so. There the whole force of the Motor Union will be concentrated on one side. As, however, it will be inadvisable, as pointed out above, for the Motor Union to act directly, it will probably be best for the Union to adopt the plan of putting itself into communication with all local automobilists and inducing them as far as possible to put their cars at the service of the candidate whom we may call the automobile candidate, and in any case refrain from lending them to his rival. The Motor Union is, we understand, taking steps to organise and establish communications with the automobilists of all different constituencies, whether members of the Union or not, with a view to carrying out some such plan of campaign. It is the most effective line to adopt in regard to a General Election. We hope to see it carried out with energy and success, and we trust that it will be efficacious and result in the return of a Legislature in general less prejudiced than the last to the requirements of the greatest industrial movement which the world has seen since the introduction of railways.

♦ ♦ ♦ A Good Omen.

WHAT the result of the election will be is, of course, at present on the knees of the gods, but as an indication that the tendencies of Sir Henry Campbell-Bannerman's Cabinet are likely to be favourable to engineering and industrial progress, we would point out that his speech at the Albert Hall contained one important pronouncement which would appear to be of decidedly happy augury for the event of his party coming into power. We refer to the Prime Minister's pronouncement on the great question of canal improvement which, with a view to the development of the motor boat as a commercial institution in this country, we have always advocated. The Premier definitely announced that the Cabinet had decided to appoint a Royal Commission to enquire into the problem of inland canal communication, which, though we are not yet acquainted with the terms of reference which will be drawn up for the Commission, will doubtless involve the consideration of developing and suiting canals for motor boat and motor barge transport. Of course this is no guarantee that the present Liberal Cabinet, if returned to power after the election, will adopt a liberal and progressive policy towards automobilism, but as straws show the way the wind blows, so a proposal of this kind may be regarded as an indication of the attitude they are likely to take up. It is, at any rate, of sufficiently good

augury to enable us to hope that in the event of the Liberal party being returned to power, the Liberal Government will not be opposed to automobile progress, whatever the general feeling of the House may be.

♦ ♦ ♦ The Conquest of the Air.

FROM information which we furnish this week in our Aeronautical column, practically all doubt as to the substantial correctness of the statements which have appeared in the French papers regarding the success of the Wright brothers in accomplishing extended free flight with a *motor-driven* aeroplane may be regarded as removed. That they have accomplished free flight, returning to the point from which they started, with an apparatus heavier than air, in which no lifting power derived from gases, enclosed in gas vessels or otherwise, is made use of, and that they have maintained themselves for a full half-hour in free flight in the atmosphere is a fact vouched for by a letter from the Wrights recently received by the Aeronautical Society of Great Britain. One could have wished possibly for a more sensational announcement, and demonstration of the facts witnessed by a satisfactory assemblage of experts. But the great things of this world are often done quietly, and if, as we believe, the facts are as we state, one of the greatest, probably the greatest of mechanical triumphs which the world has witnessed is now an accomplished fact. Man, at least two men, have learned to fly by the exercise of mechanical power, and what two have accomplished others will unquestionably learn to do in time. The thought has something of solemnity about it. Everyone with a soul above the most prosaic considerations will feel a glow of reflected triumph that the solution of the problem has come in his day. Sooner or later we knew man would add the air to the other realms he has conquered, though that has hitherto been a dream of the dim and distant future. It is too much to say that he has conquered it now, but it seems certain that two intrepid experimenters have ventured into the new province and have returned unscathed to describe their successful raid. Let us hope the appearance of their detailed description will not be long delayed.

♦ ♦ ♦ A Triumph for the Internal Combustion Engine.

THE subject is one which necessarily fascinates the automobile engineer. Apparently, no doubt, because it is he that is just accomplishing the triumph of mechanical locomotion both on the water and on *terra firma*, and naturally he regards with special sympathy the intrepid attempts to extend locomotion into the other element. It is particularly, however, as designer of the internal combustion engine that these results most appeal to him. Never before in the history of mechanical civilisation has a prime mover been devised capable of developing so high a power for so small a weight as the modern petrol-consuming internal combustion engine. Free flight by motor propulsion or even the existence of an effective navigable balloon like the Lebaudy airship were impossible before the automobile engineer had developed a machine of this extraordinary lightness for its power. If the Wright brothers have been the first whose skill and extraordinary address have enabled them to accomplish a result for which others have striven in vain, it is none the less true that the engineering agency which has perfected the modern internal combustion engine has had its share in their triumph.

PARIS SALON 1905.

(Continued.)

Commercial Vehicles.

PRACTICALLY for the first time, the industrial vehicles in the Serres de la Ville form an important exhibition by themselves, and it is almost surprising what a large

mounted on wood radius beams in much the same way as it is on the Milnes-Daimler vehicles. In some cases, like that of the Bayard, the casing of the transverse shaft is bolted directly to the stationary rear axle, instead of being carried on radius beams, while on the De Dion 'buses spur gearing is adopted in connection with their well-known transverse cardan-shafts, thus enabling the gear-box and differential case to be fixed to the frame. The majority, however, use ordinary side chains, among them being the De Dietrich, Fiat, Aries, Mors, Martini, Herald, Lacoste and Bateman, and Delaugere and Cluyette; but one or two, such as the Turgan, have side chains of the Renold "silent" pattern.

There are also some chassis on which peculiar systems of transmission have been embodied, such as the Kreiger petrol electric 'bus, in which the rear wheels are driven—through spur gearing—by independent electric motors; the petrol engine being only employed to drive the dynamo, which is mounted behind it. Another peculiar machine—which, however, is no novelty—is the "Avant-Train," shown by Messrs. Latil; this is designed for use as a fore-carriage on existing vehicles and is mounted on two wheels—which form the front wheels of the complete vehicle when in place. The wheels are driven through spur gearing by a transverse differential shaft, which is itself driven by spur gearing from the engine. An ordinary change-speed gear-box is mounted alongside the engine, which is placed transversely in the frame. On the Ducommun 'bus chassis—which was on view also at

THE PARIS SALON.—A Krieger Petrol-Electric Omnibus, having 1st and 2nd class compartments. In front is a petrol engine driving a dynamo; the rear wheels are independently driven, through spur gearing, by electric motors.

number of firms exhibit there. For the most part the chassis and cars are for commercial purposes only, although one or two are for military work, and a few are for private buyers, who require moderately heavy vehicles at their country seats. Not the least striking of the exhibits are the examples of London 'buses, but these, unfortunately, were not shown by English firms—in fact, we did not notice any English name in the whole building with the exception of that of Messrs. Thornycroft, who showed some of their famous steam vehicles. Steam vehicles, however, were not particularly well represented, the Purrey, Chaboche, and Zappa and Schars, being about the only other examples.

There is little that is very striking or novel in this commercial section, and, as with the pleasure cars, most well-known makes have already appeared at Olympia. In many cases, the principle adopted by the respective firms when entering on commercial work, has been to retain much the same system as they employed for their pleasure cars but to make every part much stronger—and there is now, we are pleased to say, less obvious omission of the extra material than there used to be. It is true, however, that some other firms have followed the Milnes-Daimler system of driving the rear road-wheels by means of internal toothed gearing—a system seldom seen on pleasure cars.

Among such vehicles is the new Panhard 'bus chassis, which also has the transverse countershaft

THE PARIS SALON.—The Sizaire-Naudin Voiturette. View showing the transverse spring in front. The axle is solid with the frame, and the steering heads are free to slide vertically through their sockets at each end. A somewhat similar arrangement was introduced on a Daimler voiturette which we illustrated in June, 1899.

Olympia—a live rear-axle is employed, but the method of driving it is peculiar. The bevel gears are duplicated, and the short shafts carrying the two bevel pinions are simultaneously driven by the spur-pinion mounted on

of this make are, as is well known, already running on the London streets. In general, however, the engines of other makes are vertical, and not in any way peculiar, although the Saurer has the ingenious system of using the engine as a brake, which we described in our last issue. The "341" type 'bus of the Saurer is the only one by which the Saurer

THE PARIS SALON.—View of the Six-wheeled Janvier Lurry. The four front wheels support a kind of bogie carriage, which is attached by inverted elliptic springs to the main-frame. All four wheels are coupled to the steering mechanism, but the bogie carriage itself always remains parallel to the frame. In the illustration one of the front wheels is resting on a large stone in order to demonstrate that it can assume that position without twisting the main frame.

the end of the propeller-shaft. In this way side thrusts are balanced, and the manufacturers also consider the design more suited to heavy work on the question of strength. Another interesting point on this chassis is the division of the propeller-shaft into two portions which are coupled together by an intermediate universal joint. This has been found necessary because the gear-box is placed close up to the engine, and the shaft would otherwise be of extreme length. A bracket attached to the frame supports the shaft close up to the universal joint.

Among curiosities, our readers will remember that the Hagen lurry has always deserved a place, and it comes as a surprise, therefore, to find that the ratchet-driven live axle has now been abandoned. Some form of gradually variable gear, however, is, apparently, still considered essential, so the manufacturers have adopted the well-known friction-disc principle, of which the Frick is an example to be seen in this country. On the Dufour chassis the two-cylinder horizontal engine drives the gear-shaft through a flat belt, and a fast-and-loose pulley arrangement does duty for a clutch. Side chains of the Renold type are used for the final transmission to the road wheels. Another chassis fitted with a horizontal engine is the Orion, in which the two cylinders are opposed and lie transversely in the frame, side chains being used to drive the rear wheels. Some 'buses

and they also afford a sharper steering lock. Of these points, the former are matters on which practical experience alone can prove their real relative values, but the advantage in the matter of steering is merely

vehicles.

ture of this year's Salon, is concerned, is the It is a point on which no little discussion is likely to take place in the near future, for some engineers are already investigating the practical advantages of the principle. At present it is in connection with 'buses and vehicles of very long wheel-base that the question is most discussed, for its more important claims—apart from the advantage of the additional support on such long frames—are that six-wheels give greater stability against overturning and skidding, and they also afford a sharper steering lock. Of these points, the former are matters on which practical experience alone can prove their real relative values, but the advantage in the matter of steering is merely

THE PARIS SALON.—View of the Lemoine brakes on the Janvier Lurry. The shoe-brakes, C, hang from the pivots, C², and are tied together by the bar, C¹. When applied, by the rods, A, which force backwards the fulcrums, A¹, the whole bracket carrying the shoe-brakes swings bodily towards the wheel, and at the same time the bands, B, tighten about the hubs. This latter action has the effect of tilting each of the short beams, B¹, which is pivoted about A¹, until its end comes against the back of the shoe-brake. In this way practically all the tensile and crushing strains are self-contained in the wheel itself, and the torsion, tending to carry away the whole mechanism, is resisted by the bolt, C².

THE PARIS SALON.—View of the six-wheeled Borderel vehicle, which has the centre wheels chain-driven and the fore and aft wheels coupled to the steering gear. The company are not pushing this principle so much for commercial work as from the standpoint that the compensated springs allow solid tyres to be used on touring cars.

dependent on the design. At present most examples in use have the centre pair of wheels constructed as driving wheels, and all the other four as steering wheels. It is obvious, therefore, that the effective wheel-base is halved. On Messrs. De Dietrich's stall is a model of a six-wheeled vehicle which, up to the time of writing, had not itself actually put in an appearance. A complete vehicle, however, is shown by Borderel and Co. in the Grand Nef, but this is not of the "heavy" type, neither is it an example to which the six-wheeled principle is particularly applicable. In the Serres de la Ville the most important example is that of the famous Renard train, which has six wheels on each of the coaches. Another vehicle shown by Janvier and Co. also has six wheels, but in this the extra pair are merely used to form a kind of bogie-carriage in front, and it does not, therefore, come within the scope of six-wheeled vehicles proper. The prototype of this latter vehicle was first exhibited in 1903, and by the same firm, it may be mentioned.

In connection with the real six-wheeled vehicles a system of compensated springs is adopted in order to equalise the load on the wheels. This is done, in spite of the fact that only one pair are driving wheels, because the unevenness of roads is assumed to be so great that there might otherwise be occasions on which the centre pair of wheels would lose their grip when passing over a hollow. Neither are the systems of compensation all similar, for elaborations have been introduced in the Renard system which are not to be found in the others. In each case, however, the method of driving the centre pair of wheels is by side chains.

Boats.

Although the boat section, in the Serres de la Ville, is very repre-

sentative, it does not call for special comment. Most of the boats are similar to those shown at Olympia, and there is little either in the design or construction which is particularly remarkable. Perhaps the largest motor boat of all is "Dietrich Cachat," a fine cruising launch fitted with roomy cabin accommodation, and in every way designed for comfortable cruising. In antithesis is "Avant Garde," a thin torpedo-shaped craft in steel, which is, of course, only suitable for racing purposes. "Antoinette" is also exhibited, and provides an excellent opportunity of inspecting the 16-cylinder 180-h.p. engine with which she is fitted, and of which we give a photograph elsewhere.

While there is no striking difference in general design between French and English-built motor-boats, it is noticeable that many of those at the Salon are fitted with a belt reversing gear, which is a form practically unused in this country. In this gear a large pulley wheel is fixed to the driving and driven shaft, and an endless belt passes under each and over a jockey-pulley placed on each side, in such a way that the motion of one pulley relatively to the other is reversed. Normally the belt hangs loose, and the engine transmits directly through the clutch. The clutch-lever is interconnected with the pivoted bracket carrying the jockey-pulleys, however, and when pulled backwards it automatically tightens the belt after disengaging the clutch.

Novelties.

At any show it is the novelties which are apt to most attract the casual visitor, and it must be admitted that there is a fascination about suddenly discovering little examples of inventive genius—too often also remarkable as instances of misplaced talent—such as it is generally possible to do in even a preliminary walk round the galleries at the Salon. This year there are among other things a pair of motor skates, a motor driven life-belt for those who cannot swim, and a turbine, of a type and principle which should have a strong—and undisputed—claim to originality. In addition, there are two other rotary engines in which the cylinders revolve, while another peculiar engine—

THE PARIS SALON.—Avant-Garde, a racing motor boat exhibited by A. Clement. The hull is made of steel and is very narrow in the beam, while the bows taper gradually to a fine knife edge. The four-cylinder engine is placed just under the raised portion of the deck.

to attend to after the flexible tube is attached, and this could be facilitated by providing a permanent fitting at the side of the frame.

Automatic Starting Devices.

Several firms are—as the result of M. Deutsch de la Meurthe's prize—now interesting themselves in the construction of devices by means of which the engine can be automatically started from the driver's seat. Of these the Mors, Renault, and Saurer are the most interesting of those actually exhibited at the Salon, although they are not the only examples there. The Mors device—illustrated last week—consists of an air-pump, attached to the frame near the driver's seat, and a small brass tank, for retaining petrol, which is fitted to the dash. Pump and tank are coupled together by a pipe, and are connected to the cylinders, so that a few strokes of the pump charges all the cylinders with "mixture." For some reason unknown, the manufacturers are apparently desirous of giving the little petrol tank an air of secrecy, for they

decline to say whether it is anything but an empty box forming a surface carburettor, and they have further taken the trouble to seal it. In order to check inquisitiveness, the catalogue states that any tank unsealed will be neither replaced nor repaired. In action, at any rate, its effect is that of a carburettor, and the initial explosion of the uncompressed gas in the "firing" cylinder is relied upon to turn the crank-shaft sufficiently to compress the next charge.

The Renault device is more complicated but less secret. Near the fly-wheel is a small 3-cylinder air-engine driving a spur-pinion which engages with a spur-wheel on the periphery of the fly-wheel. An eccentric motion is provided to engage the two wheels, but they automatically disengage directly the engine starts. Compressed air is carried in a cylindrical tank attached to the frame, and this is recharged as required by admitting exhaust gases from the petrol engine. In the Saurer self-starter

THE PARIS SALON.—View of the 180-h.p. engine in "Antoinette." There are 16 cylinders arranged diagonally, they have automatic inlet-valves and brass water-jackets. For the purposes of reversing, the exhaust-valve cam-shaft can be shifted and the engine started in the opposite direction.

which would be more interesting if it were finished—is designed to operate on the compound principle. The skates are mounted on four moderately large wheels, the back pairs being driven direct by the axle which forms the crank-shaft of the little horizontal engine. Petrol and batteries are attached to a belt which is worn by the skater. As a diversion it should have unbounded possibilities. Less interesting, although possibly even more dangerous, is the motor life belt arrangement, consisting of a box containing a small motor and its accessories, which is strapped to the user—the whole being supported by a pneumatic float. Projecting from the box is a small three-bladed screw, which is driven by the engine. Further details concerning its action are not yet available, but we imagine that a fair competency in the art of swimming would be useful, perhaps even essential, at times.

In the Retz turbine, previously mentioned, there is a vertical shaft, which is driven hydraulically by jets of water impinging on vanes. Arranged symmetrically round the central spindle are nine cylinders, also placed vertically, from which the water is discharged under pressure derived from exploding "mixture," as in a petrol engine. Each cylinder operates separately, so that the shaft obtains nine impulses per revolution. "Suction" is obtained by the effect of the water entering the cylinders and cooling the residual gases. A certain amount of compression is also obtained automatically, the various phases of the cycle being controlled by a rotary valve operated by the main shaft. It will be understood, however, that the main shaft must always be vertical.

A useful device in the shape of a mechanical tyre-pump is fitted to a Bollée chassis. It is mounted just in front of the gear-box, and is driven through spur gearing from the main shaft. In this position it is not, perhaps, extremely accessible, but there should be nothing

THE PARIS SALON.—Dietrich Cachat, one of the largest and best appointed cruising launches in the Exhibition. Alongside the boat is a large 8-cylinder marine engine, but that fitted in the boat is one exactly half this size, having four cylinders.

THE PARIS SALON.—The De Dion Bouton Company's artistic stand which, although simple, is extremely attractive, being decorated with festoons of artificial flowers.

compressed air is used direct in the cylinders of the engine, a small gear-driven reciprocating pump being used to recharge a cylindrical tank up to a pressure of about 18 atmospheres. When required to start the engine the air is controlled by a rotary valve which admits it in turn to each cylinder.

Accessories.

If only they were more compactly arranged, and less interspersed with exhibits entirely unconnected with motoring, the accessories in the Gallery would be vastly more attractive.

As things are at present, however, it is very difficult to find any particular stall, and practically impossible to make sure that everything there is to see, has been seen.

Magnetos, both of the high and low tension types, are very much in evidence, for practically all the well-known firms—among them being Simms-Bosch, Eismann, Lacoste, and Gianoli—have excellent exhibits. Lacoste and Company's stall is one of the best arranged in the gallery, and we notice that they have wisely adopted the plan of showing the elementary parts out of which their magnetos are constructed, for anything which tends to familiarise the public with details must eventually be mutually beneficial. There are also several speed indicators, shown by various firms, among which we were pleased to see

S. Smith and Sons, who, with their characteristic enterprise, have taken over a large stock of specially calibrated indicators for the French market. For finish and workmanship these English-made instruments are not surpassed by any of foreign manufacture exhibited at the Salon.

Motor clothing is always a section to which a large amount of space is devoted in the galleries, and this year is no exception. Styles, however, are somewhat different in France, and seldom, it may be said, reflect that proverbial good taste for which the Parisienne is famous. Many of the garments and hats were hideous, and quite a number of those designed for men were ridiculous. One of the most amusing exhibits we have seen anywhere is that of a firm called "Le Sport," who have installed a miniature Madame Tussaud's, in which several wax figures are grouped in unconvincing attitudes about a motor car. The variety of garments, all of which are presum-

ably appropriate to the occasion, is amazing. As an additional attraction, a long-haired fur coat, with which one of the lay figures is adorned, is offered as a consolation prize in conjunction with the official lottery.

This type of coat seems to be very popular in Paris just now, but possibly this may be explained by their price—one such being offered for sale in the Grand Boulevard at the very moderate figure of thirty-nine francs.

THE PARIS SALON.—One of the new motor omnibuses leaving the Place de la Bourse for the Grand Palais. This service was inaugurated simultaneously with the opening of the Show, and those few vehicles which are in use are only on trial. Being still a novelty to the Parisian the 'buses attracted much popular attention and are always eagerly filled.

The Qualities of Cast Iron.—Grey cast iron is so important a material in the manufacture of engine cylinders, and it varies so enormously in quality, that special interest attaches to the articles which appeared some little time ago in *Stahl und Eisen*, by Dr. H. Nathusius, on microscopic sections of this material. The researches have been mainly directed to establishing the magnetic qualities, that is to say, the suitability of certain

kinds of cast iron for dynamo construction. The extent, however, to which the material varies in homogeneity, particularly in the equable distribution of the graphite, which is so important a constituent of grey iron, according to its composition (percentage of silicon), is so striking, that the series of papers and discussion on them, published in our German contemporary, cannot fail to be of considerable interest to automobile constructors generally.

HIGH-TENSION MAGNETO IGNITION.—PART XXI.

THE LACOSTE SYSTEM—(concluded).

The Electrical Connections.

INTERNALLY the electrical connections are in no way peculiar, as the diagram of connections, Fig. 9, very

“earthing” that coil, as is generally the case in self-contained machines of this type. It is a small matter and not of any moment electrically, but it is important for the practical user, because he has to remember that it is necessary for the switch to be “on” in this case before

FIG. 9.—The Lacoste High-Tension Magneto. Diagram of internal electrical connections, showing how the windings on the Armature are connected to their respective circuits.

clearly shows when compared with others which have preceded it. Externally, however, there is one small point which it is important to notice, and that is the position of the switch. Contrary to usual practice, a switch is employed in the Lacoste system to connect the armature primary coil to its contact-breaker and not for

the magneto can be brought into use, whereas in other cases the switch is actually turned “off.” At no time does the switch on the Lacoste system make any con-

FIG. 10.—The Lacoste High-Tension Magneto. Diagram of wiring for the Lacoste Magneto when used in conjunction with ordinary battery ignition. High-tension distribution from a single trembler coil is assumed for the battery circuit, but the modifications necessary for a multiple coil system are obvious. It must be understood that, in the above diagram, the four contacts of the commutator are connected together.

FIG. 11.—The Lacoste High-Tension Magneto. View of the special High-Tension Switch, which is designed to enable this Magneto to be used in conjunction with ordinary battery ignition.

FIG. 12.—The Lacoste High-Tension Magneto. Sectional drawing of the High-Tension Switch, showing the Ball Contacts and the Switch Bar, Y², which is embedded in ebonite.

nection to earth, consequently when the magneto is out of action the armature primary coil forms an open instead of a closed circuit.

FIG. 13.—The Lacoste High-Tension Magneto. Views of the component parts of the High-Tension Switch. That shown is for a four-cylinder engine, each element is separate and can be separately operated in order to test the Ignition.

The Battery Circuit.

Although the model we have described is not specially designed for use with an alternative system of battery ignition, it can be used in this way if desired, either on a set of separate ignition-plugs or in conjunction with those employed for the battery. Of the two, the former is perhaps the simpler system, but it is not generally considered to be entirely satisfactory on account of the behaviour of the battery-circuit ignition-plugs after they have remained idle while the engine has been running on the magneto. In order to use the same plugs for both systems of ignition, however, a high-tension switch is necessary, and as it is impossible on this particular model to introduce a simple switch between the armature secondary winding and the distributor, it is necessary that a multiple switch be provided for the purpose of breaking the connection between each high-tension wire and its respective plug. For this purpose the Lacoste Company have constructed a special multiple switch which we illustrate in Figs. 11, 12, and 13. It is an ingenious device and very well made, as indeed it need be for such a purpose; the base is cut out of a solid block of ebonite, and all the terminals are attached to this portion. Neat ebonite quadrants form the moving parts, and these are mounted on a stationary spindle which is fixed to the base. They carry small spring contacts formed by steel balls in short brass tubes, and the brass rods connecting these tubes

are embedded in the ebonite. This construction is clearly indicated by the sectional drawing in Fig. 12, which also makes clear the operation of the switch. Connected to the centre terminals are the ignition-plug wires, while the two outside rows of terminals are connected respectively to the magneto and battery distributors. Each quadrant in the multiple switch can be independently operated, and any of the cylinders can therefore be immediately isolated for testing purposes.

In addition to this high-tension switch a two-way low-tension switch is necessary for dealing with the primary circuits. When changing over from one system to another it would be easier to throw over two of the four quadrants of the high-tension switch before moving the low-tension switch; after which the other two

quadrants could then be moved across. In this way the engine would be running for an instant or so on only two cylinders; but in order to avoid this it would be necessary to work both switches simultaneously—which would not be easy when they are constructed separately, and are of different patterns.

Diagrammatic connections for the duplicate systems are shown in Fig. 10, and although it has been assumed that the battery circuit is worked with a single coil, the diagram can obviously be easily applied to suit the case of a multiple coil.

Object Lessons of the Immobile Tram.—A charming spectacle of the immobility of the tramcar, resulting from the rigid manner in which the trams are restricted to their rails, was afforded not long ago at Gunnersbury, when, owing to the breakdown of a pantechicon van outside the station, some fifty electric tramcars were held up for upwards of an hour. Needless to say, with a similar service of motor 'buses there would have been no such dislocation of traffic, as the 'buses would have been able to run round the end of the damaged pantechicon without seriously congesting the traffic behind them.

APROPOS of this occurrence, a fifty minutes' block

took place recently at Walthamstow owing to the tram service. Subsequently, proceedings were taken before the magistrates against the owners of the pantechicon, which, by the way, in this case, was not broken down, but was merely unloading furniture. The magistrates maintained that the driver of the pantechicon was well within his rights, and that fifty minutes was not an unreasonable time to take for unloading such a vehicle. But think of it, but for the trams there would have been no block. As it was, not only was the tramway system paralysed, but the whole of the other ordinary traffic had to be diverted by side roads round the immovable trams.

A WOLSELEY FIRE-HOSE CAR FOR GLASGOW.

The Wolseley Fire-Hose Car, built for the Glasgow Corporation Fire Brigade, being tested by the Birmingham Brigade.

SOME interesting tests were recently made at the headquarters of the Birmingham Fire Brigade with a new Hose Car built by the Wolseley Motor Car Company for the Glasgow Corporation Fire Brigade. Throughout the tests the car carried its full complement of ten men in addition to the driver—as seen in the accompanying illustration—these men being members of the Birmingham Brigade. As a result of the experiments then conducted, it was found to take only 5 secs. for the car to reach the street, although standing in its usual position in the engine room with the motor at rest and the entrance doors closed when the alarm was given. In the traffic, its capabilities were admirably demonstrated,

and—when the road was sufficiently free of traffic—a speed of over 30 miles an hour was easily attained. Incidentally, this second test proved the effectiveness of the large double-beat fire gong, that is fixed in front, in clearing the streets for the car to pass. Finally the hill-climbing powers were fully demonstrated, for the car took the full equipment up a grade of 1 in 8 at a speed of 10 miles an hour. We learn that all the officials present were extremely satisfied with the behaviour of this useful vehicle, and it was evident to all that Glasgow is about to add a unit of very great value to the already large fire equipment possessed by that go-ahead city.

The Commercial Automobile for Australia.—Australia, particularly many of the mining districts of the great island continent, is lamentably deficient in water supply, and regular droughts frequently prevail; in fact, it appears that there is one most promising gold district in North Australia which has hitherto remained practically undeveloped owing to the difficulty of transport due to the above causes. The railways have not got as far, and horse teams have either to load themselves up with so much fodder and water for the support of the animals that they can carry little else, or be attended by another horse-drawn equipage filled up with provender and water for the first. The traction engine, too, is at a discount, owing to the scarcity of water. Recourse has been had to the camel, who drinks as little water as a “potheen” reared Irishman of Connaught, and though he has even been trained in Australia to draw carts (which he does not like), the utmost he can effect is trifling from an industrial point of view. There are

other districts in Australia, notably the districts served by the tracks which branch from the South Australian central line of railway, which are very rich in minerals, and in which the same condition of affairs prevails. Here is obviously a splendid field for the commercial light petrol lorry, which is practically independent of water, and can be designed to travel over very rough country indeed. Its presence in adequate numbers would mean the satisfactory commercial development of many parts of Australia, where progress is at present to a large extent at a standstill for the want of adequate means of transport. Let us hope that this important field of usefulness may soon be exploited by the automobile.

THE Automobile Club of Italy, which has its headquarters at Turin, has, at the Conference of Clubs held in Paris last week, been admitted into the circle of recognised Automobile Clubs.

THE PULLMAN TYRE LEVER.

ALTHOUGH the ordinary small tyre levers, which are included in the orthodox repair outfit, are admirable tools in expert hands, yet there are not a few motorists who are willing to admit that there is a difficulty in making them answer every purpose as readily as they

The Pullman Tyre Lever, which has been designed to facilitate the removal and replacement of outer covers.

could wish. To such, at any rate, the new lever introduced by Messrs. Pullman—the well-known manufac-

turers of the Pullman non-skid bands—should offer many attractions, for it is a substantial and well-made article, and it has been designed for the purpose of especially facilitating the more difficult and tedious operations connected with tyre attachment and removal. The lever is formed in two pieces, A and B. At the end of the hinged part, B, is a small hook, B¹, which engages with the far side of the wheel-rim. When thus in position, the handle, A, is used to force the heel, A¹, against the wall of the tyre, thus withdrawing the beading and facilitating the insertion of an ordinary tyre lever. When replacing a cover, the heel is used to lift the beading over the rim, in which operation it should be particularly useful with a stiff tyre on account of the long leverage obtained. It will be noticed that the hinged member is adjustable in the holes, A², and that the handle, A, has a flattened end, A³, which may be used as an ordinary lever when required.

STARTING DEVICE COMPETITION.

ON Tuesday, the 19th of December, at the Paris Automobile Salon, a jury on behalf of the Académie des Sports selected the winners of the Deutsch Prize (particulars of which have already appeared in our columns) in an open competition of devices designed to enable petrol engines to be started from the driver's seat. Of the seventeen entries only eleven actually competed, but there would have been one other—the Renault, which we illustrated last week—had that competitor not arrived just too late.

As the result of the trial, the jury have awarded equal prizes of 1,500 francs to the constructors of the Mors and Isnard devices, a prize of 1,000 francs to the Lemale, and consolation prizes of 400 francs and 200 francs to the Saurer and Pellorce respectively. There remains a sum of 500 francs which the jury have decided to use in purchasing medals, and they will award one in silver gilt to M. Deutsch, and others in bronze to each of the competitors.

Brief descriptions of some of the competing devices are given herewith, and an illustration of the Mors self-starter—which gained a first prize—appeared in our issue of December 16th.

Mors.—This is an apparatus for filling all the cylinders with uncompressed "mixture," and the firing of one charge is relied upon to be sufficient to enable the engine to compress the next; after which, of course, the engine runs normally. An air pump and a surface carburettor form the essential parts of the device, the former being adjacent to the driver's seat, the latter on the dash. It is applicable to any multi-cylinder engine, fitted with battery ignition. Weight, 10 kilograms.

"Cinogene" (M. Isnard).—With this apparatus the engine is started mechanically by the action of rack and pinion, the rack being operated by a piston which derives its power from the expansion of carbonic acid gas behind it. A supply of liquid carbonic acid is

stored in another vessel, and the gas is admitted to the starting cylinder as required; in the vessel the gas is liberated at a high pressure to replace that drawn off. Being purely mechanical and capable of imparting a high piston velocity to the engine, the apparatus is equally applicable to all engines whether single or multi-cylinder.

Battault.—In this apparatus cartridges are exploded in such a manner that they cause a wheel to revolve, the wheel being clutched on to the crank-shaft in order to start the engine. Weight 14 kilograms.

Sjelsky.—In this a hand-operated gear, acting directly on the crank-shaft, is used. Weight 5 kilograms.

Pellorce.—A series-wound electric motor and a battery of accumulators are employed to start the engine in this case. When not in use for this purpose, however, the motor forms a shunt-wound dynamo for charging the accumulators. Weight, 60 kilograms.

Buisson and Renardy.—This is a simple free-wheel ratchet device on the crank-shaft. It is operated by a foot-pedal. Weight, 8 kilograms.

Lemale.—An ordinary spiral spring is all this device consists of. It is wound up by the engine each time after it has been used.

Genevriez.—A mechanical device acting directly on the crank-shaft and operated by a hand-lever near the driver's seat.

Phillipe.—A small turbine—which is said to work equally well with compressed air, carbonic acid gas, or a head of water—is in this apparatus used to start the petrol engine.

Saurel.—Compressed air is here used in the engine direct. Its successful action depends, of course, on the pistons never remaining at rest on their dead centres. A small air pump is coupled up to the engine for the purpose of recharging the reservoir. Weight, 6 kilograms.

AERONAUTICS.

More Wright Rumours.

THERE seems little reason to entertain any longer a sceptical attitude regarding the alleged exploits of the Wright Brothers with motor-driven aeroplanes, of which we gave the particulars, as contained in a letter to Captain Ferber, in our number of December 9th. We take this view in consequence of the Aeronautical Society of Great Britain having received a letter written and signed by Mr. Wilbur Wright, stating that he and his brother had accomplished lengthy flights with a motor driven machine, and had succeeded in maintaining themselves for a full half hour in the air, executing extended flight and returning to the starting point. Taking the probabilities as regards speed attained into account, this agrees fairly well with the pronouncements in the letter published by Captain Ferber of the distances accomplished as varying from 30 to nearly 40 kiloms. The Wright Brothers have never been accused of drawing the long bow in their statements. This, however, is not the only confirmation that exists. Captain Ferber, who has all along been in direct communication with the Wright Brothers and Mr. Chanute, also received from Mr. Chanute a letter, which he published in his paper on aeronautics in the *Revue d'Artillerie*, in which Mr. Chanute personally informs Captain Ferber that he had been a witness of some of the Wrights' experiments, and on one occasion, not by any means the most recent, saw them execute a free flight of about two miles, returning to the starting-point, accomplishing this remarkable flight in a period of about five minutes. Mr. Chanute is probably the highest living authority on aeronautics, and a writer whose *bona fides* and veracity have never for a moment been impugned. The Wright Brothers are his pupils, and he would probably be the first to be invited to witness a successful flight. His testimony, therefore, is of the highest value.

There are two features of the situation which have excited scepticism. One of these is the careful avoidance of publicity cultivated by the Wright Brothers, the other is the proposal made in their letter to Captain Ferber, of placing their invention and their own knowledge and capabilities at the service of the French Government for a consideration of "un million." As regards the first of these points, the Wright Brothers, as we always have observed, have been very reticent, and it is quite possible that considerations in regard to patents may prevent them from publishing all the details of their apparatus and exploits, until such applications as they may intend to make in various countries are secured. At any rate, we know their belief to be that the majority of inventors and pioneers have "given themselves away" and interfered with their prospects by being "too previous" in publication. We have no doubt that as in the case of their record glides, they will ultimately describe their experiments in some engineering publication.

The second point, their proposal to deal with the French Government, involves less agreeable considerations. We learn from a private source that the Wright Brothers in the first instance approached the United States Government with a practically similar proposition, proposing, that is, to put what they had discovered or invented, and their unique experience and skill in aerial flight, at the disposal of the Government of the United States for a consideration of \$200,000 and that the United

States Government refused to consider the proposal on the ground that there was nothing patentable in the machine, and that as soon as the Wrights divulged its construction and management, they would be able to obtain all the necessary data free gratis and for nothing. At present, this statement cannot be accorded anything more than the consideration due to a mere rumour. We hope for the credit of mankind—and Governments—that it is untrue. The incredible meanness of it would be so unspeakable. If the rumours we hear are, as there is every ground to believe, true, here are two inventors and experimenters who have solved the problem of the ages. We may safely say, in spite of all legends about previous successful attempts of the kind, that the Wrights are the first men who have ever really flown. Quite apart from any consideration of patent rights, a solution of the problem of flight should confer a lustre upon the inhabitants of America which the Government of the States ought to be only too anxious to appropriate to some extent by making the inventors a grant, if only on the old Roman principle "for having deserved well of the Republic." For, after all, in comparison with this colossal achievement, many other human exploits sink into comparative insignificance. It was only after the refusal of their own Government, and owing to their constant communication with Captain Ferber, that the Wrights desired to approach the Government of France, not altogether, perhaps, incorrectly estimating the view that Frenchmen were likely to take, that it would be an honour to their country to have become the patrons of the first men who had solved the problem of flight, even if the successful experimenters did not happen to be Frenchmen. We believe the negotiations are still in progress, and we trust they will be successful. For experimenters in a department involving so much expenditure, the Wrights must be regarded as far from well-to-do. Any grants of this kind they might obtain—and their demands, it must be admitted, are moderate—would be to recoup them for past expenditure, and to assist them in further research. Surely their services are worth acquiring by any Government!

We trust the Government of the United States has not made a final refusal. If it has, it will probably find that it has come to a very short-sighted decision. The position is a dilemma. The secrets of success are either due to special construction of the apparatus, some subtle proportionment of surface to length or other general arrangement of parts, in which case they are patentable, or the success is due to skill in the manipulation of an apparatus which presents no novel features of a patentable kind. Even if the second assumption of the dilemma is the true one, the Wrights may still have something to dispose of. It is quite conceivable that they may be able to teach others how to use their apparatus, even though, as we have already pointed out, this kind of skill in the animal world has been only communicable by heredity and not by instruction. In Mr. Wells' delightful romance, "When the Sleeper Wakes," it will be remembered that the possessors of the secrets involved in the successful manipulation of the "aeropiles" formed a closed corporation which jealously guarded what it knew. If the art of manipulating the Wright machine can only be learned slowly, and they have spent a long period upon it, it does not follow that their assistance would not be of the greatest value in teaching others. Flight on

the Wright's principle, therefore, either involves a patentable machine, in which case we may be sure that it has been patented, or it can be taught (perhaps both statements are true to a certain extent). Surely to secure them with their experience as teachers, would be worth the while of any military or civilised power in the world.

REFERRING to the experiments of Messrs. Frost and Hutchison on wing flight, of which we gave an illustrated résumé on May 27th, Mr. Henry Sutton writes from Melbourne to draw our attention to the fact that he communicated to the Aeronautical Society in 1878 a paper on "Wing Flight," including most of the results which the Cambridge experimenters have attained. He had an apparatus driven by clockwork, not unlike the arrangement of the electric motor with goose's wings which Messrs. Frost and Hutchison employed, and it gave very similar results. Mr. Sutton's theory of the actual bird flight differs somewhat from Mr. Hutchison's, as he denies the valvular effect of the up-and-down movement. He maintains that the upward stroke has an effect in producing forward motion. The prospects of flapping-wing-flight are at the present moment, needless to say, far behind those which have been attained with aeroplanes, though of course the form of apparatus which will ultimately triumph cannot even as yet be guessed at. In any case, it is of historical interest to find that an experimenter like Mr. Sutton, who has since done much in other directions—his heavy oil carburettor and car, for instance, were described by us some time ago—was making substantial contributions to aeronautical problems as early as in 1878.

CAPTAIN BALDWIN, the designer of air-ships of the navigable balloon type in the United States, has brought out a further development of his well-known "Arrow," which was the only machine of its kind to give at all a satisfactory account of itself at the more or less abortive competition at the St. Louis World's Fair. The new Baldwin airship is on the same lines as its predecessors, but the gas-vessel is somewhat stumpier than in the previous cases, though its capacity has been increased to 16,000 cubic feet of hydrogen gas. It is constructed of Japanese silk, oiled inside and out, and covered by a square meshed net of 72 cotton seine twine. The hull of the present airship has also been shortened in length from 100 feet to 50 feet, while still remaining of the general Santos Dumont type excepting that the propeller is in front and an enlarged flag-shaped rudder behind. Instead, however, of the members of the

keel being of steel tubing as formerly, they are constructed of Oregon spruce, which is said to be wonderfully tough and well suited for the purpose. The skeleton of the rudder is also made of the same material. It is in the $7\frac{1}{2}$ -h.p. motor, however, that the chief improvements have been introduced, the present machine consisting of two air-cooled finned cylinders inclined to one another at an angle of 45 degrees—the whole in this respect resembling a bicycle motor. Additional exhaust ports are provided, to assist in releasing the burnt gases, and the intake valves are mechanically actuated. A built-up flywheel is employed, and the gasoline tank has a capacity of two gallons. Captain Baldwin has been stating the conclusions at which he arrives at some length. Amongst these are that when an airship of the type he employs exceeds a very moderate speed, it becomes unmanageable. He also proposes the use of inclined aeroplanes for guiding it, in addition to the ordinary rudder. These observations read somewhat amusingly in light of the records of the Lebaudy airship, with which speeds of 25 miles an hour and upwards have been attained without any unmanageability, though this possibly may be due to the fact that the Lebaudy airship has for the last two years employed aeroplanes for steering and maintaining stability.

SOME experiments, not without interest, to the solution of the aeroplane problem, are reported from the United States. An elaborate machine, which might perhaps be described as a combination of the Wright and Langley types of apparatus, was towed by a tug on the Hudson River against the wind, when it ultimately rose to some 500 ft. in the air, carrying Mr. C. K. Hamilton, a professional aeronaut, who succeeded in manipulating it like a great kite tolerably satisfactorily. The machine appears to have given proof of greater stability than is usually possessed by an ordinary kite, though ultimately when the pull upon its rope was diminished it made a dive into the water, the aeronaut being rescued by a boat. He is very sanguine as to the capabilities of the machine, and believes it will be possible to manipulate it if supplied with motor equipment and propellers. Aeronauts almost invariably are exceedingly sanguine. The machine consists of two aeroplanes, one behind the other and braced together, each of these structures consisting of an upper and lower flat plane, with inclined planes joining the ends of the upper plane with the centre of the lower plane, vertical steering rudders projecting from the upper plane. The construction is said to give great rigidity, and the inclined planes are said to increase the lateral stability.

MOTOR CYCLING.

Auto-Cycle Club.—Tickets are now ready for the Auto-Cycle Club's annual dinner, to be held at the Criterion Restaurant, Piccadilly Circus, on January 17th, price 7s. 6d. each. Amongst the visitors who have already intimated their intention of being present are Sir W. Martin Conway and Earl Russell.

The first quarterly trial will start from the Chequer's Hotel, Uxbridge, over the following route:—Uxbridge, High Wycombe, Dashwood Hill, Wheatley, Bletchington, Banbury (lunch), returning *via* Bicester, Aylesbury, Berkhamstead, Chesham, Amersham, Beaconsfield, Uxbridge. This route was used in the Passenger Motor Cycle Trials last October. The event is open to all classes of motor cycles, and certificates will be awarded to all machines making a non-stop run, which will report upon hill-climbing, ease of starting and control, accessibility, silencer, stand and luggage carrier. The entry fees are one guinea for the trade, and 10s. 6d. for private owners.

THE Land's End to John o' Groat's Run being organised by the Auto Cycle Club for the coming year is receiving a considerable amount of support from a number of enthusiastic motor cyclists. Many of the "end to end" performers are coming forward and helping with their past experience, so that the event should prove, under such practical advice, a big success. Private owners are to be encouraged to enter, by the offer of a reduced entrance fee and special prizes, and we shall hope to see a good entry list resulting in a large proportion getting through and merely demonstrating the advance which has been made in reliability in the modern motor cycle, as considerable benefit should accrue to those firms who have gallantly stuck to this section of the industry.

THE Open Hill Climb for Tri-cars being organised by the Lewisham A.C., has been fixed to take place on River Hill on February 10th.

MOTOR BOATING.

A POPULAR RENDEZVOUS FOR MOTOR BOATING.—Durnham-on-Crouch Quay, showing Durnham Yacht Club en fête for one of the British Motor Boat Club's meetings last season.

MOTOR BOATING IN FRANCE—NEW REGULATIONS.

As a result of the Navigation Congress, the Yachting Club of France working in conjunction with the Automobile Club of France have passed a series of new rules, some of which—particularly those that determine the motor-power by the fuel or current consumption—constitute a radical departure from past usage. The following are amongst the fresh provisions:—

All boats are divided into three categories—*Canots* (pleasure boats of not more than 18 m. length), *Yachts* (pleasure boats of greater length than 18 m.), and *Bateaux à usages divers* (industrial craft), but, generally speaking, the rules refer to the first two categories, although they are also to apply so far as possible, and if required, to the third category.

Four sub-divisions—according to the nature of the power plant—are then specified, with the general idea that the craft belonging to each shall, as a rule, compete separately. These are:—For boats with (a) internal-combustion engines, (b) electric motors, (c) ordinary steam plants, and (d) flash steam systems; in no case does the nature of the fuel used affect the classification.

Then comes a further classification by which the boats in each sub-division are split up into (1) racers, and (2) cruisers, but it is stipulated that any boat can compete in both these classes, provided that it has obtained an official certificate for both.

Racers are placed together in either of four categories according to length—those of 8 m. or less, those of over 8 m. but not over 12 m., those of between 12 m. and 18 m., and those exceeding 18 m. Similarly there are four categories for the cruisers, but in this case according to their rating, this being calculated on a $\frac{L \times C}{P}$ formula which determines their handicap and time allowance. Although cruisers belonging to different categories may be allowed to race together, these categories define the four classes as those having a rating of 8 or less, of 8 to 37, of 37 to 124, and of more than 124, respectively. For the purposes of the formula $\frac{L \times C}{P}$, the length (expressed in metres) will be the arithmetical mean between that

on the water-line and that over all, while the displacement (P), expressed in metric *tonnes*, is to be taken on a salt-water basis with fuel tanks full, but without “*equipage*” on board. The motor-power (C) is, for all types of cruiser, based on the fuel (or, in the case of electric, on the current) consumption per hour, and is to be settled in advance by an official measurer, who will make a full load test of two hours’ duration before any certificate is issued; both the speed of the motor and the calculated mean speed of the boat will be noted on the certificate. A further rule insists upon a “reversing” gear being available on all craft, whether *canots* or *yachts*, and whether they be racers or cruisers.

THE MODIFIED M.M.A. RULES.

At a special meeting, called recently for the purpose, the Marine Motor Association decided to make some very important alterations and modifications to their rules. The new rules are as follows:—

The old Measurement Rules from the word “Classes” on page 16 onwards to the bottom of page 18 are cancelled, and the following new rules substituted:—

CLASSES.

	Rating.
Class A ... Not exceeding	75
„ B ... Exceeding 75, but not exceeding ...	250
„ C ... Exceeding 250, but not exceeding ...	1,000
„ D ... Exceeding	1,000

There are no restrictions on beam, freeboard, or m.p., in Classes, A, B, C, and D.

Cruiser Classes.—Sub-divisions of the Cruiser Classes:—

Sub-division 1 ... Not exceeding	25 ft. o.a.
„ 2 ... Exceeding 25 ft., but not exceeding ..	50 ft. o.a.
„ 3 ... Exceeding	50 ft. o.a.

Every cruiser to have a fixed cabin extending the whole width at the level of the gunwale, and for a length not less than 25 per cent. of the overall length of the vessel, with a minimum clear head-room of 4 ft. 6 in. throughout the length of the cabin, and for a width of not less than 2 ft. in the centre.

No vessel to be admitted to the Cruiser Classes whose motor

power exceeds $3\frac{1}{2}$ m.p. per ton, such tonnage to be measured by the following formula:—

$$\text{Tonnage} = (L - B) B \times \frac{1}{2} B.$$

94

Where L = Length overall.

B = Greatest breadth to outside of plank.

No vessel to be admitted to the Cruiser Classes whose lowest freeboard, wherever found, is less than 25 per cent. of her greatest beam to outside of plank.

MEASUREMENT FEES.

		£	s.	d.
Class A	...	1	1	0
" B	...	2	2	0
" C	...	3	3	0
" D	...	4	4	0
Cruiser Classes	Sub-division 1	1	1	0
	" 2	2	2	0
	" 3	3	3	0

The Official Measurer shall collect the fees before measuring.

ADDITIONAL RULES.

Every vessel racing under the Rules of the Association must be entered in the Association's Register of Motor Vessels. The charge for such registration to be 2s. 6d., payable on application.

The Association will allot to any vessel so registered a number, which shall be considered the racing number of the vessel, and which shall be displayed upon a flag rigidly extended at least 2 ft. above the deck.

The number flags are not to be less in size than 12 ins. by 15 ins.; figures to be block Arabic, not less than 8 ins. high and $1\frac{1}{4}$ ins. thick. The flags will not be supplied by the Association.

The number flags for the various classes to be of the following colours:—

Class A	...	Red Ground, White Figures.
" B	...	White " Black "
" C	...	Light Green Ground, White Figures.
" D	...	Yellow Ground, Black Figures.
Cruiser Classes	...	Dark Blue " White "

Every boat racing under the Association's Rules is to be fitted with an efficient exhaust silencer.

The present time scale is cancelled, and Mr. Hope's curves of results of actual performances during the past season is to be used as a basis for the construction of a new time scale, which shall equalise as far as possible the chances of boats of varying types when racing together.

Monaco Meeting.—If the entry of a number of splendid motor boats can be relied upon to make a successful meeting, the Monaco meeting next year should prove a record. Already some of the best-known boats are reported to be amongst those which will take part, including 2 Napier racers, in addition to a 6-cylinder Napier of Mr. Lionel de Rothschild's, a Brooke racer, Trèfle-a-Quatre, New Trèfle, an Antoinette racer with a Levavasseur engine of 600-h.p. (48 cylinders), 3 Martinis, several De Dietrichs, "Loodet III.," an 18-metre Serpollet craft, 2 Richard-Brasier racers, 3 Mercedes, 2 Panhards, a Fiat, and several Italas.

CLUBS AND ASSOCIATIONS.

British Motor Boat Club.—Two lectures have been arranged to be held in the Craven Hotel, Craven Street, Strand, W.C. The first will be on "Screw Propellers," and will take place on January 18th, at 8 p.m., and will be given by Mr. Ramsay Smith.

The second lecture will be held about the middle of February, and will be on "The Practical Handling of Motor Boats," by Lieut. W. Windham.

An informal dinner will be arranged at the club before each lecture.

Society of Motor Omnibus Engineers, Limited.—We have received some further particulars of this organisation. The Society has for its objects, amongst others:—

1. To promote, encourage, and facilitate the growth of the carriage of passengers, and of mails or goods if carried in conjunction with passengers, by means of motor vehicles other than on permanent ways, for profit (herein referred to in general as the said motor traffic), and to promote the science and practice of motor omnibus engineering, and all branches thereof.
2. To promote the consideration and discussion of all questions affecting directly or indirectly the said motor traffic, and generally to watch over and protect the interests, as far as possible, of persons engaged in such traffic.
3. To enable persons interested in the profession and practice of the said motor traffic to meet and discuss, and to correspond, and generally to facilitate the interchange of ideas respecting improvements in the various branches of the science of motor omnibus traction and the publication and intercommunication of ideas respecting improvements in the said science.
4. To give to the legislature, and to public bodies and others facilities for conferring with and ascertaining the views of persons engaged or interested in the said motor traffic as regards matters directly or indirectly affecting that traffic or trades allied to it.
5. To promote excellence and perfection in the construction in that class of motor vehicles as are or might be commendable and serviceable in the said motor omnibus traffic or manufacturing trades.
6. To admit any persons to be either associate or honorary members of the company on such terms and to confer on them such rights and privileges as may seem expedient.

Membership is limited to engineers or engineer managers in charge of motor omnibus undertakings, or their approved assistant engineers or assistant engineer managers, and provision is made for both associate membership and full membership. The annual subscription is one guinea, with an entrance fee of a like amount. In

order to enable manufacturers and other persons interested in the work of the Society to become connected with it, subscribers of not less than three guineas per annum to the funds of the Society may be admitted and enrolled as associates.

It is provided, in regard to the constitution of the Council, that there shall be not less than five nor more than twenty members, and that not less than one-third of the Council shall be engaged in business partly or exclusively outside a radius of 20 miles from Charing Cross. We gave the names of the first Council last week.

The only honorary officers of the Society will be a President and Vice-President, the principal active officers, who will be elected by the Council, being a Chairman and Vice-Chairman.

At the last meeting of the General Committee of the Motor Union, the three following gentlemen were elected to life membership of the Union:—Mr. G. T. Langridge (Epsom), Mr. H. H. J. Baring, Esq. (Loughton), and Mr. F. H. Faviell, Esq. (Loughton).

THE Roads Improvement Association, Incorporated, announce a change of offices to 1, Albemarle Street, Piccadilly, facing St. James's Street, where all communications should for the future be addressed to the honorary secretary, Mr. Rees Jeffreys.

RACES, RECORDS, AND TRIALS.

MIDDLETON PNEUMATIC HUB TRIAL.—The Florentia car (the light one in the centre), fitted with Middleton Pneumatic Hubs, at the Wheatsheaf Hotel, Sunningdale, upon the last day of the trial on December 22nd. The other cars in the picture are all fitted with similar hubs, and were driven out to "receive" their companion on the nearing of the completion of its task.

Middleton Pneumatic Hub Trial.—This trial, under the observation of the Automobile Club, over a distance of 4,000 miles, which commenced on November 21st, has been continued daily, as far as possible, since, terminated on Friday of last week. The car used was a 16-20-h.p. 4-cylinder Florentia. The test has been a successful one, especially in view of the heavy state of the roads which prevailed at the early part of the trial. The first week's run was 978 miles, one of the pneumatic tubes, owing to a leaky valve, having to be replaced at the end of 900 $\frac{1}{2}$ miles. The mileage for the second week was 819 $\frac{1}{2}$ miles, one day having been lost through necessary adjustments to the car. One hub during the week required pumping up and another was replaced. After this the hubs ran through the next week without any repairs or adjustments of any kind, and on Friday, December 22nd, the test was successfully concluded over the 4,000 miles with a few more miles to spare. The official details of the trial are at present not available.

Scottish Reliability Trial for 1906.—The date for this trial, under the auspices of the Scottish A.C., has been tentatively fixed for the second week in June.

THE start of the Tyre Trials of the A.C.G.B.I. has been postponed from February 1st to February 15th, the last day for entry now being fixed for January 31st. The Speedometer and the Lamp Trials, the rules of which we published last week, will be held at the same time, and in conjunction with the cars entered for the Tyre Trials.

BARON HENRI DE ROTHSCHILD has offered, through the French Académie des Sports, a prize of 1,000 francs for the best registering speedometer for motor cars.

Road Records.—The A.C. de France announce officially that they have recorded the following record performances, all of which we have, at the time of their accomplishment, duly announced in our pages.

1. Flying Kilometre for Voiturettes: Barriaux, Vulpes car, 33 $\frac{3}{8}$ s.
2. Flying Kilometre for Heavy Vehicles: F. Dufaux, on Dufaux Racer, 23 secs.
3. Flying 5 Kilometres for Heavy Vehicles: Colomb, on Mors car, in 2m. 0 $\frac{1}{2}$ s.

IT has been decided at the International Conference of Automobile Clubs in Paris that disqualification of any driver by any individual club, shall be at once notified to the rest of the clubs by telegram, the telegram to be confirmed in writing the same day, such notice of disqualification to take immediate effect, as from the receipt of the telegram.

1906 Fixtures.—At the Calendar Congress, held in Paris last week, the majority of the more important dates for events during 1906 were arranged, the chief of which we give below. The idea of this congress is essentially a good one, and judging by the expressions of opinion of the delegates who attended it, is likely to be in future years more officially recognised. By this means we trust that it will be of more practical value than hitherto, as experience has shown that, in spite of the arrangement of dates made at the congress in previous years, with very few exceptions they have been altered and shifted about two and three times before finality has been reached. Probably in the same way this year it will be found to be equally misleading, but as a guide to the general scheme of events for the coming year the dates named are of interest. The French club have been unable to fix definitely the date

either of their big racing event or of their 5,000 kiloms. tourist vehicle contest, but from the middle of June to the middle of July has been tentatively "ear-marked" for the French club, this period probably including, in addition to the speed race, the heavy vehicle contest and a Paris-London motor 'bus event. The following are the other main dates:—

Jan. 12-25	...	Brussels Salon.
Feb. 6-18	...	Berlin Exhibition.
Mar. 8-15	...	Anti-Skid Trials (A.C. Seine and Oise).
" 8-21	...	Cannes Motor Week.
" 15-28	...	Vienna Exhibition.
" 25-31	...	Nice Motor Week.
April 1-15	...	Monaco Motor Boat Meeting.
" 2-8	...	Milan-San Remo Voiturette Trial.
" 16	...	Meyan Cup at Nice (Motor Boats).
" 17-24	...	Long Distance Mediterranean Race (Motor Boats).
May 6	...	Targa Florio.
" 13	...	Voiturette Competition (A.C. Austria).
" 13-24	...	Motor Cycle Tour de France (A.C.F.).
" 15-31	...	Endurance Competition (A.C. Milan).
" 27	...	French Eliminating Trial (Moto Club de France).
June 1-3	...	Electric Vehicle Contest (A.C.F.).
" 9-15	...	Herkomer Cup.
" 28-29	...	Kiel Regatta.
July 14-17	...	Ostend Meeting (Flanders A.C.)
" 22	...	Havre Speed Mile Trials (<i>L'Auto</i>).
Aug. 6-18	...	Marine Fortnight (British Motor Boat Club).
" 14-19	...	Coupe de Trouville.
" "	...	Circuit des Ardennes.
" 26-Sept. 2	...	Brescia Week.
Sept. 2	...	Florio Cup.
" 10-15	...	One-Third Litre Criterium (<i>L'Auto</i>).
" 15-16	...	Mont Ventoux Hill Climb.
" 23	...	Semmering Hill Climb.
" 23	...	Auto Cycle Club de France Cup.
Oct. 7	...	Chateau Thierry Hill Climb (<i>L'Auto</i>).
" 14	...	Maison Lafitte Motor Boat Meeting (<i>L'Auto</i>).
" 21	...	Speed Kilometre on the Flat and Hill.
" 28	...	Gaillon Hill Climb (<i>L'Auto</i>).
Nov. 1-16	...	Berlin Exhibition.
Dec. 2	...	Coupe de Salon (<i>L'Auto</i>).
" 7-24	...	Paris Automobile Salon.

Contest of Public Vehicles for Town Use.—A contest took place in Paris last week for motor hackney vehicles plying for hire on the Paris streets. A good list of entries was secured, the vehicles being divided into two classes, viz., (1) petrol and steam vehicles, and (2) electric vehicles, these being again subdivided into categories according to their cost value. The test was over a distance of about 100 kiloms. over ordinary streets in Paris, and the judges in determining their classing, under the rules, took into consideration the regularity of running, fuel consumption, and appearance and comfort of the body of the vehicle. Any involuntary stoppages were noted throughout the run, and electric vehicles, when recharging or taking on fresh batteries, were treated, so far as stopping time was concerned, as broken down.

The first place in the awards in the Petrol Sec-

tion falls to the Aries with a gold medal, the Automoto gaining second with a silver-gilt medal. In the Electric Vehicle Class the Vedrine firm obtain the gold medal, the Electromobile Company the silver-gilt medal. The winners of silver medals and diploma recipients are given in our table.

The following are the vehicles which took part, together with the times occupied:—

Class I.—Steam and Petrol Cars.

CAT. II.—Total Value 6,000 to 8,000 francs:—

No.	Car.	Weight laden kilogs.	Time (100 kil.) h. m. s.	Medals.
14	Ader	1,668	3 45 58	Silver.
19	Bayard	1,390	4 52 0	

CAT. III.—Value 8,000 to 12,000 francs:—

9	Aries	1,584	3 56 42	Gold.
7	Brouhot	1,812	3 58 10	Silver.
15	De Dion	1,456	4 4 35	Silver.
17	Gladiator	1,599	4 24 16	*
2	l'Electrique	1,440	4 47 33	*
13	Vinot	1,654	5 2 19	*
5	Brouhot	1,457	6 34 48	

CAT. IV.—Value over 12,000 francs:—

6	Delaugère	1,791	3 39 30	Silver.
1	De Dietrich	1,676	3 46 20	Silver.
20	Automoto	1,931	3 53 54	Silver Gilt.
11	Florentia	1,833	4 15 59	*
18	Clement	1,582	4 27 14	*
10	Aries	1,810	4 30 54	Silver.
22	Pilain	2,010	4 43 10	*
12	Decauville	1,720	4 47 49	*
3	Buire	1,740	5 22 0	*

* Diploma of the A.C. de France.

Class II.—Electric Vehicles.

CAT. II.—Value 5,000 to 8,000 francs:—

30	Galliette	1,580	Abandoned.
----	-----------	-------	------------

CAT. III.—Value 8,000 to 12,000 francs:—

37	Jeanteaud	1,618	Side-slipped and broke axle.
----	-----------	-------	------------------------------

CAT. IV.—Value over 12,000 francs:—

36	Krieger	2,107	4 25 28	Silver.
39	Vedrine	2,066	4 33 12	Gold.
41	Electromobile	2,128	4 43 40	Silver Gilt.
31	l'Electrique	2,723	6 49 53	Silver.
34	Milde	2,080		
35	Krieger	2,031	Collided.	
40	l'Electromotion	2,238		

Official Sketch Map of the Brescia Circuit, where the important Italian racing events will take place in September next. The contour surrounding the course conveys a rough idea of the "give and take" character of the roads.

== PROPOSED COURSE. --- MAIN ROADS. . . . RAILWAYS.

THE BIG FRENCH RACE, 1906.—Map of the proposed Fontainebleau Course, of which we gave some pictures last week. The intricate nature of the three circuits, as then described by us, can be gathered more clearly from this sketch map.

Trials of Suction Gas Plants.—It is announced by the Royal Agricultural Society of England that they intend holding some important trials of suction gas producers and engines in connection with the Derby Show next year, and propose to award a Gold Medal and a Silver

Medal as first and second prizes. The following is a *résumé* of the regulations under which the trials are to be conducted.

Each plant is to be of from 15 to 20-b.h.p. The engines are to be fixed by the competitors in a special shed, which will subsequently form a part of the Show, and every engine is to be fitted with all necessary testing apparatus to the approval of the Society's consulting engineer, including dynamometer brake, water trough for cooling the fly-wheel, indicator-gear, revolution-counter, and explosion-counter.

Specifications and detailed drawings must be sent to the secretary at 13, Hanover Street, W., on or before March 15th; and the actual date on which the Trials are to commence is Monday, June 18th.

The actual trials will consist of long duration runs primarily using anthracite coal, but other runs will also be made with coke as fuel; in both cases the fuel will be provided by the Society. For the first full-load trial, a fixed quantity of coal will be given to each competitor, who will be required to start the plant from cold, and to get the engine running at full power as soon as possible. The time of lighting up will be noted, but the time recorded, so far as fuel consumption is concerned, will be taken from the commencement of the run. After running for nine hours under constant load, the engines will be shut down for the night, to resume running on the following day, and at the conclusion of the trials all unconsumed coal will be credited to each competitor. Half-load trials on precisely the same lines, but of shorter duration will then follow, after which there will be a "no-load" trial of two hours' duration, although the coal consumption will not be recorded in connection with it. A stipulation is made that the fan is not to be worked by hand during the half-load and no-load trials.

It only remains to be said that the special points to which attention will be directed are: (1) attendance necessary; (2) general design—including facility of cleaning—and space occupied; (3) regularity of working; (4) fuel and water consumption; (5) price; (6) relative proportions of gas producer and engine; (7) volume swept by piston relative to b.h.p.

MIDDLETON PNEUMATIC HUB TRIAL.—Completion of the 4,000 miles on Friday last. Another car, also fitted with Middleton hubs, meeting the Florentia Car on the road upon which the official trial has taken place. A little incident "stage-managed" for the purpose of recording the completion of the 4,000th mile. Note the "special" milestone.

CORRESPONDENCE.

£150 FLYING MACHINES.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—With reference to the recent paragraph in your paper giving particulars of some information about a new flying machine, said to have been conveyed to the Press by me, I may mention that this is a misunderstanding. The information was obtained from a report of a lecture I gave on "Aeronautics" before the Royal Engineers at their Institution at Chatham, and is not quite correct.

The first full-sized machine would probably cost about £150 to build, and further machines a good deal less. The model that I tested was on a small scale, with one square foot of active surface.

Since I made my tests the inventor has got still better results, as he tells me that he obtained a lift of 283 lbs. per brake-horse-power with an active surface equal to 16 square feet per lb. raised. When the driving power was increased the total weight lifted was trebled, thus reducing the active area to 5 square feet per lb. lifted, but the efficiency was reduced, the weight lifted per brake-horse-power being only 138 lbs. The calculated lift of aeroplanes and screws varies according to different authorities from 122 to 231 lbs. per horse-power.

The importance of these tests is the fact that none of the true flying machines have as yet obtained anything like this sustaining power per horse-power used. Professor Langley's complete machine weighed 30 lbs., had 54 square feet area, and developed 14-h.p., that is, the lift was 20 per brake-horse-power. Sir Hiram Maxim's lift at 42 miles per hour was about 10,000 lbs. with 360-h.p., or nearly 29 lbs. per horse-power. Few airships using balloons have a lifting capacity from the gas of more than 200 lbs. per brake-horse-power, and have the additional weight and resistance of the balloon.

With the above lift of 283 lbs. the speed was not taken, but was probably about 5 or 6 miles per hour. The speed could be increased to practically anything within reason, the lifting power then being proportionally decreased. I think that better results will be obtained from the larger-sized machines.

Yours faithfully,
F. L. RAWSON.

Dec. 20th.

6-CYLINDER CARS.

To the Editor of THE AUTOMOTOR JOURNAL.

SIR,—I have just returned from a visit to the Automobile Show in France, and must express my admiration for the magnificent lighting effects that they have been able to obtain in the beautiful Grand Palais. They are of a character which we cannot hope to attain over here until we get an exhibition building suitable for the dignity and the importance of the automobile trade.

As one, however, most keenly interested in the continued success of the British automobile industry, I was very pleased to find the trend of events in regard to manufactures, and to find that there was an absolute opportunity for the British trade to take up a position, at any rate in the high-class trade, that would put them to a large extent in an unassailable position, unless sweeping changes come along which the British trade had not foreseen. I refer particularly to the 6-cylinder development. I know, and have known for some considerable time, that this 6-cylinder principle for powerful cars must come and must be embodied on every type of powerful car, for the public realise and appreciate the advantages of six cylinders, and the necessity for having not less than six cylinders if they wish a powerful motor car to run with the maximum of comfort.

I have preached the gospel of six cylinders more or less strongly for a long time now, and personally, in the way of orders and fortune, I am reaping a benefit even beyond my dreams, but the time has now come when I realise that a market is opening up far greater than my firm can hope to keep for itself, or meet more than a portion of the demand, and I therefore want those British manufacturers whose works are capable of making 6-cylinder cars, to really learn all about them, and, if after learning about them they are not convinced of the business waiting for all of us who can manufacture this style of car, then, at any rate, they will only have themselves to blame if they are not able to meet the business as it arrives, and to assist them in this direction I shall be only too pleased to put a 6-cylinder car at the disposal of genuine British manufacturers for, say, any reasonable period—a day or so—to try for themselves the advantages the 6-cylinder principle holds, and

why I know and so strongly believe that for absolutely the best class powerful car, it must oust the 4-cylinder. It is not yet too late for those in Great Britain to take this opportunity of getting into the business that is waiting for them.

Abroad we have the Panhard trying the principle, so far without commercial success, because I admit there are difficulties in the manufacture of six cylinders. We have the Mercedes (in the person of Herr Maybach, works' manager and designer) admitting in the public press that the main object of builders of the 6-cylinder engine is to simplify the change-speed-gear mechanism and also to reduce the necessity for frequent speed or rather gear changes. He, however, qualifies his remarks by saying that these good points are only required on a racing car, and therefore a Mercedes racer for 1906 will have six cylinders.

Personally, I believe, and I think everyone will agree with me who can see at all ahead, that this is merely a stepping stone to the introduction of a touring Mercedes of six cylinders for 1907. We find both Clement and Gladiator with 6-cylinder touring cars for 1906.

It was heard from the lips of M. Théry that M. Brasier was working on a 6-cylinder racer, and that Théry certainly thought that six cylinders were absolutely necessary for a racing car for 1906. It is also rumoured that the Hotchkiss Company are also working on a 6-cylinder.

There was, of course, a Cotterau 6-cylinder car at the Exhibition, but obviously in the experimental stages, and when on top of all this you read extracts from newspapers from countries so far divided as the *Horseless Age*, of New York, of November 22nd, the *Allgemeine Automobil Zeitung*, of Vienna, the *Automobile*, of America, of December 7th, *Les Sports*, of December 14th, and *L'Auto*, another French paper, all putting forward various and different arguments in favour of six cylinders, it should be clear to those who ought to be able to see ahead the rush that is setting in for 6-cylinder cars due to their merits, and which rush, if the British manufacturer will take my advice, he will be ready to meet and get a certain start on the bulk of Continental makers.

He is then manufacturing a British designed vehicle, and every other country in the world is in the position of merely being a copyist of that British vehicle. It is a chance for the British manufacturer, and he should take it, and I can give him some help and will willingly do it.

The Napier factory is open to anyone to see that nearly all the orders in hand are for 6-cylinder cars, and they are being manufactured by hundreds as fast as possible.

Dec. 21st.

Yours truly,
S. F. EDGE.

Sportsmen and the Automobile.—Masters of Hounds, with a few exceptions, have not been at all slow to recognise the utility of the automobile from the sporting point of view. In fact, it is very largely due to their initiative that the automobile has recently enjoyed so much popularity in bringing members of the field to meets, while its superiority to the ordinary dog-cart or trap in enabling something of a hunt to be seen from the roads, has rendered it a general favourite with those who enjoy the sport from this second line of attack. Mr. Sanders, a Master of Hounds in Somersetshire, who is one of the many sound converts amongst M.F.H.'s to the use of the automobile, has recently written a letter to Mr. Henry Norman, M.P., full of praise for the virtues of the small light car, particularly in his district, where the roads are unsuited to heavier types. He is enthusiastic in regard to the extent to which the light car enables him to dispense with railway journeys. He is a great horse owner, and, as such, his testimony to the fact that horses are not nearly as frightened by motors as by traction engines or steam rollers, is interesting. The notion of children being scared off the roads is, in his opinion, all moonshine. Mr. Sanders keeps some five-and-twenty horses, so he is a good authority on equine peculiarities, in which connection he states that a coach-and-four coming along the road frightens an ordinary horse a great deal more than an automobile does.

An artistic and useful paper-knife has reached us, which has been issued to their friends by Messrs. Charles Jarrott and Letts, Limited, at 45, Great Marlborough Street, can, for the mere asking, obtain one of these useful desk companions. The embossed design on the handle is that of the Lorraine Cross and Thistle.

London Town.

(London: Raphael Tuck and Sons. Price 1s. net.)

THIS is another of the many excellent examples of the perfection to which coloured process work for the illustration of books has been brought. The idea of the pamphlet is that of a fragmentary guide to London, arranged in the form of a walk from Fenchurch Street to the Marble Arch, taking most of the principal objects of interest on the way. Certainly the coloured illustrations are admirable, though they give a scarcely accurate impression of London as enjoying the clearness of atmosphere which since the Jubilee year has been seldom observed. Of course, in a work of this kind the difficulty is to know what to leave out, but where so much has been successfully included it seems rather strange that historic Whitehall should be omitted altogether. The coloured process work is, on the whole, superior to the descriptions by which the illustrations are accompanied, in which crudities of style are sometimes observable, as where Westminster Abbey, "this monument to England's glory," is described as "the pride of every Britisher." It is, perhaps, rather rash, too, to inform us that Cleopatra's Needle was quarried while Moses was in the land of the Pharaohs, as most Egyptologists agree that it is distinctly older than Moses. And why, oh!

why, has the terrible Temple griffin been selected as a frontispiece? As an example, however, of what the book is intended to illustrate, namely, the application of coloured process work to book engraving, "London Town" is eminently successful.

The Fan.

By CHAS. H. INNES.

(Manchester: The Technical Publishing Company. Price 4s.)

THIS little work is a good practical treatise on the fan, though of course the fans dealt with are mainly large ventilating fans, requiring high power for driving them, and designed either for delivering air under pressure or ventilating mines and buildings. The question of designing highly efficient fans is not one that presents itself in an acute form to the automobile engineer, as there is no particular necessity to obtain a high degree of efficiency in the fans that are arranged for drawing air through radiators. At the same time the subject may be useful to works managers in deciding the rival merits of fans for ventilating purposes on a large scale.

Auto Fun. Pictures and Comments from "Life."

(London: Geo. G. Harrap and Co. Price 5s.)

THIS is a reproduction of a number of cartoons on automobile topics which have appeared in our transatlantic contemporary, *Life*. The drawings are admirable, and in many cases the humour appeals even to the prosaic resident in the British Islands, but on the whole one feels, on going through the book, that one requires, in some respects, to be educated up to American humour, and we cannot altogether appreciate it in its fulness without a preliminary course of training. A good laugh may be safely predicted, however, for all, particularly the initiated.

A New Anti-Shock Device.—It is not a very frequent occurrence for an automobilist to be pitched out of his car with such verve as to come precisely head downwards either on the high road, against an opposing wall, or an unsympathetic policeman, but should such an occurrence take place, a well-known outfitter of Cheapside has provided a palliative. It takes the form of an ordinary cloth cap with an internal crown of pneumatically inflated indiarubber balls. These deaden the shock of impact as far as the skull is concerned, though they apparently transfer it to the neck. At least that is what the office-boy says who has been put to try it against a brick wall for ten minutes steadily. That it prevents the impact affecting the brain of the wearer was satisfactorily demonstrated, as no difference from his usual smartness was noticed, as regards the experimenter, at the termination of the tests. We are anxious to organise a demonstration of the virtues of the appliance by precipitation from an automobile, and hope to arrange for a representative of the inventor to come out with us in a car wearing the cap, when we will unexpectedly clap on the brakes fully, and await the result with confidence. We are pleased to know that "the balls always remain inflated," and that it is not, therefore, necessary for the wearer to feel for his pneumatic pump whenever he anticipates an accident.

THE Hackney Furnishing Company, who are, as everyone knows, very go-ahead people, are organising a special service for facilitating the transaction of business with provincial purchasers. A four-in-hand coach is to leave their premises every Monday morning, and travel through the principal towns of the home counties the names of which will be duly advertised, together with the address at which the representative of the Company will stay. As the

Sir Archibald and Lady Macdonald in their new 40-h.p. "De Dietrich Car.

AMERICAN inventiveness has always been displayed in the improvements they effect in language. The latest of these is the new plural, "chasses" for "chassis," for which our contemporary, the *Motor World*, is responsible. Of course, "crises" is the plural of "crisis," but then one word is Latin and the other French, which, after all, sometimes makes a difference.

SOME proceedings, in which the decision can hardly be regarded as anything but extraordinary, took place recently before the Lord Chief Justice and two other judges sitting *in banco* in reference to the Brighton Speed Trials on the Madeira Road last summer. An application was made on behalf of a Brighton ratepayer for a *certiorari* to quash two orders made to the Borough Treasurer to pay £2,500 and £550 out of the general district fund. The Lord Chief Justice observed that a merely extravagant expenditure which was here alleged, as the expenditure was involved for putting a tarmac surface on the Madeira Road, was not a point that could be raised as a question of law, and Mr. Justice Ridley asked if it was for the benefit of the motor car people rather than for that of the ratepayers. Mr. Casson, counsel for the objecting ratepayer, then at once made the amazing statement that the Automobile Club took all the profits and the Corporation had to bear all the expenditure, and that they got none of the receipts. On hearing this statement, the Lord Chief Justice at once said, "You may take a rule." When the actual action comes to be tried, however, it may be safely assumed that evidence of this astonishing statement will be required.

coach goes through the principal streets of the towns it visits, it will only be necessary for those intending to transact business to signal the driver to stop, when they will at once receive a visit from the firm's representative, who will explain the methods and system of business adopted and show sample models and photographs of goods, so that buyers may be saved the trouble of a journey to London. Clients of the Company who wish to use the coach to travel from one town to another will be allowed to do so. Considering the general enterprise of the Hackney Furnishing Company, we are somewhat surprised to find them adopting the old-fashioned coach-and-four for their propaganda. A suitably constructed motor vehicle would be much more expeditious and far better suited to their requirements, while it would, most undoubtedly, bring in more business.

A particularly fine vehicle is that shown in the above illustration, this being one of the latest four-cylinder 25-30-h.p. cars that the Ariel Motor Company are building for next season. It is fitted with a special double phaeton Tulip body, to the order of Mr. W. Garnett, of Clitheroe, Lancashire, and a considerable amount of storage space has been rendered available at the back, as well as beneath the front seats. Instead of the usual style of upholstery, with dust-collecting buttons, this portion of the body is finished off on a new principle that gives the seats an exceptionally tidy appearance, while the comfort of the occupants at the back has been carefully studied inasmuch as the seat affords ample room for three persons, and the wide doors can be swung full open—quite clear of the mud-guards.

The Paris Salon.—On Sunday last, the Paris Automobile Salon finally closed its doors for this year, after having run its brilliant course. The effect of holding the Olympia Show first, however, has taught the French makers a sharp lesson. British buyers have been scarce, if not altogether absent, and the leading firms have not been slow to grasp the trend of affairs. Already they are planning to forestall Olympia Show next year by having an exhibition of their own as early as October. What the A.C. de France will say to this move, and how they will meet it or bow to it, remains to be seen. At present the date for their next Salon is provisionally fixed for the same as this year—December 8 to 24. The awards for stand decorations, construction of body work, &c., are as usual announced. Amongst those high up in this list of honours for cars, we notice:—Grand Prix: De Dion Bouton, Delaunay-Belleville, Bayard, Darracq. Gold medals: Hotchkiss, Richard-Brasier, Renault, De Dietrich. Silver-gilt: Fiat, Mildé, Coteriau, Nala, Leon Bollee, Gobron-Brillie, &c. In the sections for lamps and tyres, Duceillier is to the front with a gold medal; Michelin and Samson secure silver-gilt medals; Dunlop, Continental, and Falconnet-Perodeaud receive silver medals. In the Salon Lottery, which was drawn on Sunday, the big prizes are an 8-h.p. De Dion Bouton car and a "Gallia" electric vehicle. Ticket No. 343,388 has won the former, and No. 94,667 the latter.

AN indignation meeting of cats has been held in the metropolis, and other similar meetings will, we believe, soon take place in the provinces, the felines having learned that the latest form of fashionable wear for motoring consists of cat-skin gloves with the fur and all intact, the fur of a well-nourished pussy being found particularly glossy and attractive. Possibly this new fashion may account for the phenomenon which residents in the metropolis have recently noted of a very decided diminution in the number of London cats. It

One of the 1906 model 15-h.p. four-cylinder De Dion-Bouton Cars just introduced into this country. The car is somewhat lighter than the 1905 model. The engine has a bore of 90 mm. and a stroke of 100 mm., and is controlled by a hand-lever above the steering wheel which operates on the throttle valve. Particulars of other new models for 1906 appeared in our issue of October 28th. Mons. Bardin, the manager of the De Dion Bouton Paris depot, is at the wheel, and another very prominent official of the company, M. Lemarchand, head of the frame department, is in the tonneau.

is a better fate than the Herne Hill Physiological Laboratory!

A WRITER in the *Lady of Fashion* has been working herself into quite a "state" over the ill-treatment of London 'bus horses, in regard to which she is in most cases thoroughly justified. "Surely," she concludes, referring, of course, to the replacement of the horse 'bus by the motor vehicle, "it was God himself who invented motors." Considering that some 20,000 horses have already been displaced from tram service by the electrification of the tram lines, the effect which will be produced when motor omnibuses become universal can be more easily imagined than estimated. Whether the displaced horses will for the time being find themselves better off than they were before may, considering the manner in which useless horses are generally treated by their supporters and admirers, reasonably be doubted.

ONE of our Asiatic readers sends us from Siam a little monthly magazine, entitled *Siam Engineering* (The Journal of the Engineering Society of Siam). This is a brightly written and interesting engineering publication, and we note with special satisfaction that a large part of the present number is devoted to the automobile question, a paper read before the society, by Mr. Westenholz, dealing with the proposal to construct a motor road to Penang. From Bangkok, we learn that motors have become a regular feature of the landscape, and that the roads are so good that they hardly ever puncture their tyres except when they are frequently compelled to cross the tram-lines. Other references to automobile topics appear in *Siam Engineering*, and one of distinct interest to car owners and tyre companies is that except for very light cars the pneumatic tyre appears to be a failure in the tropical East, owing no doubt to the general high prevailing temperature.

One of the latest 12-15-h.p. Touring Cars now being supplied by the New Arrol-Johnston Company. This model is of the same type as those which secured first and fourth places in the Tourist Trophy Race this year. In last week's issue we completed a fully illustrated article, in which the construction of this very satisfactory type of vehicle was described in detail.

THE baby that was born on the top of the Vanguard omnibus, and which has been christened "Vanrita," to whose notorious advent into this world we referred at the time, has created quite a furore amongst employees of the London Motor Omnibus Company, and they have all clubbed together to make a presentation to the infant on the solemn and auspicious occasion of its being transferred from long clothes to short.

AN "omnichauf," which is a new though not very euphonious term for the driver of a motor 'bus, is said to be in something of a quandary for a means of paying homage in the customary omnibus style to Lord Rothschild, who every Christmas presents a very large number of omnibus drivers in the Metropolis with a brace of pheasants. The omnibus drivers in consequence always decorate their whip or harness with the Rothschild colours. Some of the lively writers in the daily Press want to know what the "omnichauf" is to tie his colours on to. Perhaps, without the exercise of too much ingenuity, he might try the steering wheel.

Reduced facsimile of the Diplome d'Honneur issued by the Automobile Club of Hungary in connection with their Exhibition last June. This has been awarded to the Wolseley Tool and Motor Car Company, whose cars were exhibited there, as we recorded at the time of the opening of the Show.

COMMERCIAL POINTS.

RECENTLY we published a photograph of Mr. John Hargreaves' Napier racer, which had been converted into a luxurious touring car. We learn that this conversion was made by Messrs. Hill and Ball, of Yeovil, the whole body being designed and the work carried out by that firm.

CAPTAIN DEASY will be joined, as directors for the purpose of exploiting the new "all-British" Deasy car, by Sir Richard Waldie-Griffith, of Hendresyde Park, Kelso, Sir Robert W. B. Jardine, director of the Caledonian Railway, of Castle Mill, Lockerbie, and Mr. K. H. Buchanan, director of H. H. P. Deasy and Company, Limited, general manager of the London Power Omnibus Company, Limited, and director of the Welsbach Incandescent Gas Light Company, Limited.

THE Duke of Portland, late Master of the Horse, and Earl Sefton, the new Master of the Horse, are both owners of 40-h.p. De Dietrich cars.

THE Road Carrying Company, Ltd., of Liverpool, have been considerably extending their business, and we understand are doing an increasing trade in handling well-known cars. They have just supplied Richard-Brasier cars to Sir Thomas Neave, Bart., Mr. R. E. Birch, and Mr. E. S. Edgar, and through the company, Sir William B. Forwood has secured an Argyll model. Sir William, it will be remembered, is a member of the Royal Commission sitting on the Motor Car Acts. In the commercial vehicle department, the Liverpool Bon Marché has just placed a repeat order for two delivery vans, making four in all, which this firm have now in constant work. Altogether, we learn from Mr. E. A. Rosenheim, the manager, that trade in Liverpool is pretty brisk.

"SIX AND SIXTY."—Pictures from an original season's greeting card from Mr. and Mrs. Charles Jarrott, who are at the wheels of the "6" and the "60" in the left and right pictures, respectively.

MR. S. F. EDGE writes us in regard to a note which recently appeared in reference to a green door of a motor car being found on the road. He informs us that he has just heard that the Duke of Connaught lost such a door from his 6-cylinder Napier when returning from Woolwich the other day. Possibly the finder may, upon learning this, be anxious to return his find to its Royal owner.

THE Motor Exchange of Great Britain propose holding on the 17th of January their first auction sale at their premises at Boundary Road, Notting Hill, W. The auction will take place in the grounds of the company, where intending purchasers can see the cars running round the track during the sale. For two days previous any motorist can inspect the cars which will be for sale, and will be able to try them round the track.

A NEW catalogue is to hand from the Electromobile Company, Limited, which, like all the productions of this company, is a pattern of neatness and conciseness. The methods already adopted by them has made the electric brougham one of the most conspicuous objects of the London streets, and thereby helped forward in many directions the conversion of anti-motorists. A new system has been introduced by the company which is likely to be beneficial to their customers, as owners can now "job" from them the batteries and tyres, and thus effect a considerable saving in the first cost of a carriage. The company's garage being in such a central position as Curzon Street, Mayfair, is important, as enabling them at a moment's call to quickly reach any point of fashionable London.

THE Samson Leather Treads and Tyre Company, Limited, advise us that they have removed to larger and more convenient premises at No. 1, New Burlington Street, W.

THE Metropolitan Garage Association have opened premises at 12a, Palace Street, Victoria, opposite Buckingham Palace. The firm inform us they have made arrangements for hiring out cars of the latest pattern for either short or long periods, and they are able to supply lock-up coach houses for any sized cars, so that owners can contract for permanently garaging their vehicles with them. Facilities for repairs are provided on the premises, and petrol, lubricating oil, etc., are stocked.

MESSRS. SEYMOURS, LIMITED, write us as follows:—"It having come to our notice that our name is being associated with that of the late "Dixi Motors, Limited," we shall esteem it a favour if you would kindly make known through the medium of your valuable paper that, although this Company has taken over the sole agency of the "Dixi" car, it has otherwise no further connection whatever with the before-mentioned Company.

COMPANY DOINGS.

Palmer Tyre, Limited.—At the eleventh annual general meeting of the Palmer Tyre, Limited, the chairman, Major Leonard Darwin, presided, and in moving the adoption of the report, said the results were satisfactory, considering the severe competition and the high price of rubber. They had made a new agreement for management with the Indiarubber, Gutta-percha, and Telegraph Works Company, under which they would receive for about fourteen years a royalty of at least £5,000, and possibly more. This year it amounted to £6,753 14s. 4d. The capital of the Company had also been increased from £48,000 to £60,000, in order to purchase from the Indiarubber Company certain valuable patent rights in connection with motor tyres. They had, in short, sacrificed their immediate prospects to make their position quite secure, for several years to come. It would, he said, be obvious from the accounts that a larger dividend than 6 per cent. might have been declared, but by placing a considerable sum to reserve annually, the directors hoped that the business would be worth its par value at the end of the present management agreement.

With regard to motor tyres, he thought that their present season's make was very much superior to what they had made in the past.

The Scottish Motor Engineering Company, Limited.—The first statutory meeting of the Company was held at Granton on Thursday last week, Mr. Wm. Alexander, chairman, presiding. In moving the adoption of the report, Mr. Alexander spoke of the aims, progress and prospects of the Company, while in regard to the property itself, he said the shareholders had that day an opportunity of inspecting and satisfying themselves as to the value of the buildings, plant, and machinery they had acquired.

The response to the directors' call for capital had been favourably received, and he took that opportunity of clearly stating that the Scottish Motor Engineering Company, Limited, was *not* a re-construction of Stirling's Motor Construction Company, Limited, whose works they had secured at less than one-third of the original cost. The drawings, patterns, and plans acquired in the purchased assets, and on which no value was placed, had already been consigned to the scrap-heap. The present company had now started on its career commercially and productively as an entirely fresh industrial concern.

Dealing briefly with the prospects and policy to be pursued, and the manufactures to be carried out at Granton, the chairman said that the present demand for reliable motor omnibuses was far in excess of the supply. So far, little British capital had been turned to account to meet the demand, and the foreigners, being first in the field, had, and were still reaping a fruitful harvest. Judging by the success of several prominent builders of pleasure vehicles, and the popularity of their productions, the "Britisher" was quite as far

LAND AND WATER.—A pair of Christmas greeting cards. That on the left, from the well-known motorist, Mr. Roger H. Fuller, on "My First Motor, 1898," brings back memories of the past and suggests contrasts with present designs. The breezy right-hand picture of the motor boat, "Quicksilver," comes from Mr. James A. Smith, M.I.N.A.

advanced as the foreigner in motor construction, and the cry "All British" was justly and rapidly gaining ground.

"The Granton" chassis now nearing completion, and which would be ready for the market early in the new year would be "All British" and "Best British." Mr. Clingoe, and Mr. Drake, formerly works manager to the Daimler Company, and now acting in a similar capacity at Granton, had given the design much careful study, and were responsible for its production. Standardization of parts would be a prominent feature in the manufacture.

They were already besieged with inquiries from buyers on all sides, but until the first chassis had been subjected to every test and proved itself equal to the standard claimed, they had refused to negotiate sales. Early in the New Year they would, when ready, know where to market the Company's output.

The repairing of motors of all kinds was also a branch which would be developed, and two large shops had been fitted out to undertake the work.

NEW COMPANIES REGISTERED.

Austin Motor Company (Limited), Longbridge Works, Longbridge, The Lickey, Worcestershire.—Capital, £50,000 in £1 shares. First directors, H. Austin and F. Kayser.

Dart Motor 'Bus Company (Limited).—Capital £100 in £1 shares.

BRITISH PATENT SPECIFICATIONS. Selected and Abridged by James D. Roots, M.L.Mech.E. Thanet House, Temple Bar, London.

The first date given is the date of application ; the second, at the end, the date of the advertisement of the acceptance of the complete specification .

28977. 30th October, 1904. Improvements in and relating to Oil Separators and Vaporisers for use with Oil Engines. Tom Thornycroft and John I. Thornycroft and Co., Limited, Church Wharf, Chis-

wick. This invention has for its object to effect more or less complete separation of particles of heavy oil and tarry matter from a mixture of vaporised heavy oil and air whilst on its way from an oil vaporiser to the cylinder of an internal combustion engine, and also to provide an improved construction of oil vaporiser. There is one figure, a central vertical section. The separator comprises a casing, *a*, that is approximately of inverted truncated conical shape externally, and has a similarly shaped internal chamber, *b*, provided with an inwardly-extending spiral or screw-like rib, *c*, between the convolutions of which is a groove, *d*, of decreasing diameter. The spiral passage, *c*, is connected at *e*, to the end

Deal, Dover, and Folkestone Motor Omnibus Company (Limited).—Capital, £5,000 in £1 shares.

Q.C.E.D.A. Syndicate (Limited).—Capital, £60 in £1 shares. Object, to acquire patents relating to quick-charging and efficient-discharging accumulators.

Standard Gas Engine Company (Limited), 9, Chapel Street, Preston.—Capital, £10,000 in £1 shares. Object, to acquire the business of engineers, internal combustion engine makers, &c., carried on by O. Sumner and J. L. Leyland at Marsh Lane, Preston, Lancashire, as the Standard Oil Engine Company. First directors, O. Sumner, J. L. Leyland, R. E. Smalley, W. H. Woods, T. H. Clarke, N. Miller, W. Worden, and J. Clarke.

Standard Motor Agency (London) (Limited).—Capital, £100 in 1s. shares.

W. L. Thompson (Limited), 83, Anlaby Road, Kingston-upon-Hull.—Capital, £500 in £1 shares. Object, to acquire the business of W. L. Thompson, 83, Anlaby Road, Hull, manufacturers of cycles, velocipedes, and motor cycles. First directors, W. L. Thompson, H. E. Bowen, and Mrs. E. A. Thompson.

Henry Whitlock (Limited).—Capital, £6,625 in £1 shares. Object, to acquire the business carried on at 14, Leonard Place, Kensington, W., as Henry Whitlock, Limited, of coach, carriage, motor car, and cab builders, &c. First directors, H. F. Gidden and R. J. Harrison.
